UNITED STATES DEPARTMENT OF THE INTERIOR • James G. Watt, Secretary

BUREAU OF MINES

As the Nation's principal conservation agency, the Department of the Interior has basic responsibilities to protect and conserve our land and water, energy and minerals, fish and wildlife, and park and recreation areas, and for the wise use of all those resources. The Department also has a major responsibility for American Indian reservation communities and for the people who live in Island Territories under U.S. administration.

Foreword

The Federal Government, through the Minerals Yearbook and its predecessor volumes, has reported annually on mineral industry activities for 96 years. This edition discusses the performance of the worldwide mineral industry during 1977. In addition to statistical data, the volumes provide background information to assist in interpreting the year's developments. Content of the individual volumes follows:

Volume I, Metals and Minerals, contains chapters on virtually all metallic and nonmetallic mineral commodities important to the domestic economy. In addition, it includes a general review chapter on the mineral industries, a chapter on mining and quarrying trends, and a statistical summary.

Volume II, Area Reports: Domestic, contains chapters on the mineral industry of each of the 50 States, the U.S. island possessions in the Pacific Ocean and the Caribbean Sea, and the Commonwealth of Puerto Rico. This volume also has a statistical summary, identical to that in Volume I.

Volume III, Area Reports: International, contains the latest available mineral data on more than 130 foreign countries and discusses the importance of minerals to the economies of these nations. A separate chapter reviews the international minerals industry in general and its relationship to the world economy.

The Bureau of Mines continually strives to improve the value of its publications to its users. Therefore, the constructive comments and suggestions of readers of the Yearbook will be welcomed.

Acknowledgments

The Bureau of Mines, in preparing this volume, utilized extensively statistical and other basic data on mineral production, consumption, and trade provided by various foreign government mineral and statistical agencies through a variety of official publications. The cooperation and assistance of these agencies is gratefully acknowledged. Statistical and informational material was also obtained from airgrams of the U.S. Department of State, from United Nations publications, and from the domestic and foreign technical and trade press. Of particular help in preparing this volume were the routine and special reports submitted by the minerals, petroleum, economic, and commercial officers and other members of the Department of State. Their contributions are sincerely appreciated.

The text and tables of this volume were prepared by the staff of the Branch of Foreign Data, Division of Production/Consumption Data Collection and Interpretation. Final correlation and checking of this volume were performed by the Branch of Publication Support Services of the Division of Publication.

The regimes of some countries reviewed in this volume are not recognized by the U.S. Government. The information contained herein is technical and statistical in nature and is not construed as conflicting with or being contradictory of U.S. policies toward these countries.

Minerals in the World Economy

By Charles L. Kimbell[1]

The year 1977 generally was a year of growth in overall world mineral industry activity, although there were downturns in major elements of the world's iron and steel industries. The sharp upturns in market economy nation activities that were noted in 1976, following the reduced performance levels of 1975, were moderated, and in the centrally planned economy nations, overall mineral industry activity apparently continued to increase, but at a pace in keeping with that of 1976 rather than at the higher rates of the earlier 1970's.

Noteworthy during the year, if only in a negative sense, was the inability of world powers to reach any significant agreement on issues relating to deep seabed mining. Interest from a commercial viewpoint centered around deposits or so-called manganese nodules. These materials, which indeed are chiefly manganese in terms of their content on a quantitative basis, really were of commercial interest primarily for their copper, nickel, and cobalt content. Participants at the Third United Nations Law of the Sea Conference looked into seabed mining rights, but reached no mutually agreeable decisions.

PRODUCTION

The estimated value of world crude mineral production in 1977 was $197,600 million in terms of constant 1973 dollars, about 5% above the revised 1976 level of $188,200 million. The value increase was somewhat higher than the actual quantitative increase, however, because of higher unit prices in 1977 than in 1976. The following tabulation summarizes approximate data on value of world mineral production for selected years:

Digitized by Google

Year	Billion constant 1973 dollars	
	Value of 53[1] major crude mineral commodities[2]	Value of all crude mineral commodities[3]
1950	46.2	52.6
1953	60.3	69.3
1958	77.4	93.0
1963	85.6	104.9
1968	99.2	120.2
1973	159.2	189.6
1974	162.0	183.7
1975	159.2	178.1
1976	167.6	188.2
1977	175.9	197.6

[1]The list of commodities included appears in table 5 of the 1974 edition of this chapter; one commodity covered in 1950-68 (beryl) is excluded from the 1973-77 figures, but the overall impact of this omission is regarded as insignificant.
[2]Data for all years except 1974-77 are as reported in Annales des Mines, December 1975, p. 13; data for 1974-77 are extrapolated from the 1973 Annales des Mines figures on the basis of the United Nations index of extractive industry production in the United Nations Monthly Bulletin of Statistics, August 1979, p. xiv.
[3]Data extrapolated from those values for 53 commodities to compensate for commodities not included in the source of that data. For details on the basis of extrapolation, see relevant text in the 1974 edition of this chapter under "Value of World Mineral Production."

The foregoing data belittle the role of the mineral industry in the world economy, however, for they represent an approximation of the value of minerals in their crudest form—the actual production from mines, quarries, and wells—and not the enhanced value that results from beneficiation, smelting, refining, and other equivalent downstream processing. Further, no allowance is made in these values for the value added in transporting mineral materials from the production centers to those places where they are ultimately consumed. If the value added through processing—smelting of metals, refining of oil, and manufacture of basic materials such as cement and fertilizers—were included, a 1977 figure on the order of $470,000 million could be regarded as a conservative estimate of the value of output of primary mineral processing plants, to which a further as yet unestimated increment could be added for secondary metals processing. Moreover, it should be noted that the crude and processed mineral commodities constitute the overwhelming dominant share of the total raw material base for all manufacturing endeavors, as well as a significant requirement for the agricultural industries because of that industry's need for fertilizers of mineral origin.

PRODUCTION INDEX PATTERNS

The following tabulation summarizes the growth in world mineral industry output as reflected by the United Nations indexes for extractive mineral industry components:

Year	Index Numbers (1970=100)			
	Coal	Crude petroleum and natural gas	Metals	Total
1973	96	122	105	114
1974	96	125	107	116
1975	99	120	102	114
1976	100	130	105	120
1977	101	139	106	126

Source: United Nations. Monthly Bulletin of Statistics, August 1979, v. 33, No. 8, New York, 1979, p. xiv.

Digitized by Google

Comparison between the world extractive industry indexes in the foregoing tabulation and the indexes for processing sectors of the mineral industry presented in the following tabulation demonstrate the substantially higher levels of growth in production value for downstream products:

Year	Index numbers (1970=100)		
	Nonmetallic mineral products	Chemicals, petroleum, coal and rubber products	Base metals
1973	124	129	128
1974	128	135	135
1975	126	131	133
1976	136	146	145
1977	141	155	155

Source: United Nations. Monthly Bulletin of Statistics, August 1979, v. 33, No. 8, New York, 1979, p. xv.

For details on differences in mineral industry index pattern growth for various world areas, the reader is referred to the source publication for the foregoing tabulations.

QUANTITATIVE COMMODITY OUTPUT

Total world production of 87 distinct mineral commodities and/or specific forms of mineral commodities is given in table 1 for 1975-77. Of these commodities, 65 registered gains and 22 recorded declines in 1977 relative to 1976 output levels, compared with 62 reporting gains and 25 recording declines between 1975 and 1976. Of the 45 metal commodities listed, 31 were produced in greater quantities in 1977 than in 1976; of the 31 nonmetal commodities recorded, 24 were produced at higher levels in 1977 than in 1976; and among the 11 fuels listed, all but one were produced in greater quantities in 1977 than in 1976. Probably the most notable declines in output in 1977 were those recorded for iron ore, pig iron, ferroalloys, and crude steel.

No viable means exists to sum up the overall production performance of the nonfuel mineral industry, and for these commodities, exactitudes on value are not available for detailed review. Among the fuel commodities, however, a pattern of overall growth can be demonstrated by United Nations data in which all fuels are reduced to a common energy equivalent basis. The following tabulation summarizes world energy output for 1973-77:

Year	Million metric tons, standard coal equivalent				
	Coal	Crude petroleum and natural gas liquids	Natural gas	Hydro and nuclear electricity	Total
1973	2,426	4,247	1,539	186	8,398
1974	2,457	4,261	1,560	209	8,487
1975	2,577	4,054	1,568	224	[1]8,422
1976	2,650	4,381	1,633	232	8,896
1977	2,763	4,569	1,671	250	[1]9,254

[1]Data may not add to totals shown because of independent rounding.

Source: United Nations. World Energy Supplies 1973-78. Statistical Papers, Series J, No. 22, New York 1979, p. 14.

Total output of energy in all forms increased 4% between 1976 and 1977, compared with an increase of 5.6% between 1975 and 1976.

TRADE

In 1977, the aggregate value of total world trade in mineral commodities reached $386,300 million, an increase of nearly 10% from the previous record high set in 1976. The following tabulation summarizes the growth pattern in mineral commodity trade for 1970-77:

Digitized by Google

Year	Estimated value of all mineral commodities traded[1] (millions)	Change from previous year (percent)	Mineral commodities share of all commodities traded (percent)
1970	$83,558	+17.4	26.8
1971	[r]91,191	+9.1	26.3
1972[r]	103,760	+13.8	25.1
1973	[r]151,800	[r]+46.3	26.5
1974[r]	324,900	+114.0	38.8
1975[r]	312,100	-3.9	35.8
1976	352,700	+13.0	35.7
1977	386,300	+9.5	34.4

[r]Revised.
[1]Value estimated from data on major mineral commodity trade appearing in table 5, to which has been added a factor for all mineral commodities not included in that table.

The phenomenal increases registered in the value of mineral trade in 1973 and 1974 and the continued high levels of 1975-77 almost exclusively reflect the huge growth in the price for fuels rather than any increase in the quantity of material being moved in trade. Between 1972 and 1973, when there was a 46.3% increase in value of exports, the weight of vessel loadings increased by only 13%, and between 1973 and 1974, when the export value increase was 114%, the growth in weight of vessel loadings was only 1.1%. The total amount of growth in mineral export value, of course, was not entirely directly the result of growth in fuel cost, but a significant share of the increase in value of nonfuel mineral exports was the result of higher energy costs involved in their production, processing, and transportation.

Viewing the decline in mineral trade value in 1975, it should be noted that the value drop of 3.9% was lower than the corresponding shortfall in quantity of goods loaded, which totaled almost 7.3%. Thus, while the growth rate for mineral commodity value as measured by mineral commodity exports was diminshed in 1975, it was by no means halted.

Moving on to 1976 and 1977, the growths of 13% and 9.5%, respectively, over the previous year, that were recorded for mineral commodity exports again were smaller than the 10.4% and 2.5% growths registered for weight of loadings of vessels in those years, reflecting again the continued upward trend of unit prices, first for fuels themselves and second for other mineral commodities, with the latter in part due to higher energy costs for their production, processing, and transport.

Table 2 provides data on the distribution of value of world mineral trade in major mineral commodity groups, and a comparison between the value of these major mineral commodity groups and the value of total commodity trade. The data in this table on trade in major mineral commodities also served as the basis for estimation of the value of total world mineral commodity trade which appears in the tabulation at the beginning of this section. Table 3 is self-explanatory, giving the distribution of value of world export trade in major mineral commodity groups by group. The consistent rise in the share of the total accounted for by mineral fuels during 1972-77 is the most noteworthy single fact shown.

Table 4 shows the change in value of each of the major mineral commodity groups, as well as of total commodity trade, during 1972-77 on the basis of percent change over the previous year.

In previous editions of this chapter, three additional tables on mineral trade were provided (see tables 8-10, in the 1976 edition). Limitations of time and staff precluded their preparation for inclusion in this chapter, but the reader may derive this data for himself from the June 1978 and May 1979 editions of the United Nations Monthly Bulletin of Statistics. Details provided by these tables included the role of major mineral commodity trade in total trade of various major world areas (table 8 in the 1976 edition), the distribution of exports and imports in each of the major mineral commodity groups by major areas of origin and destination (table 9, in the 1976 edition), and the distribution of total mineral commodity exports from each major region by region of destination (table 10 in the 1976 edition).

Digitized by Google

CONSUMPTION

NONFUEL MINERAL COMMODITIES

Although time has not permitted a detailed compilation of data on world consumption of major mineral commodities, an upturn in consumption of most metals is suggested on the basis of partial data, and available reports on nonmetals suggest that use of most such materials also increased in 1977.

MINERAL FUEL COMMODITIES

Data published by the United Nations indicate that there was a 3.2% increase in worldwide energy consumption between 1976 and 1977, substantially below the 6.0% growth level between 1975 and 1976, but well ahead of the .3% increase between 1974 and 1975. The following tabulation summarizes world total mineral fuel consumption by major fuel types in recent years:

Year	Million metric tons of standard coal equivalent				
	Solid fuels	Liquid fuels	Natural and imported gas	Hydro, nuclear, and imported electricity	Total
1973	2,452	3,578	1,517	187	7,734
1974	2,489	3,535	1,545	210	7,779
1975	2,516	3,523	1,545	224	7,808
1976	2,646	3,770	1,633	231	8,280
1977	2,744	3,896	1,651	250	8,541

Although the share of the total accounted for by each of the listed fuels has altered only slightly during the five years covered by the tabulation, there were generally increases in the percentage share accounted for by solid fuels and by hydroelectric and nuclear power, over the total period, with compensatory declines in liquid fuels, and natural gas.

INVESTMENT

Available information on selected industrial sectors of market economy countries and on total U.S. mineral industry investment, together with general indications and spot reporting of individual investments in other world areas, indicate an increase in investment levels in 1977, at least in terms of current dollars. It is less than clear, however, whether these increases in current dollars represented any growth in investment in terms of tangible assets, because of the inflationary trend throughout the market economy world.

Moreover, not all mineral industry sectors registered increases in current dollar investments. Table 5 summarizes annual investment expenditures in the iron and steel industry in selected countries for 1975-77. In 1975, steel industry investment was over 10% below the 1974 level reflecting the sharp downturn in overall economic activity in 1975. The sharply higher figure for 1976 reflects both an increase in investment and the spiraling inflationary pattern, thus the apparent 50.7% increase did not buy 50.7% more equipment. The downturn in 1977 (9.6% below the 1976 level) was indicative of an even more significant decline in investment in terms of actual burning power because of the continued inflationary trend. Every country and country group represented in the table registered declines in current dollar investment level except Spain, Japan, and Turkey; and among these upturns, only that of Japan was really significant. This pattern reflected the generally poor economic condition of West European and American steel producers.

Table 6 provides data on total U.S. direct foreign investment by the mining, smelting,

Digitized by Google

and refining industry and the petroleum industry for 1974-75 and geographic detail as well as totals for 1976-77. In the case of the mining, smelting, and refining industry, there was but a negligible increase in investment between 1976 and 1977, and in the petroleum industry, there was an 8.7% growth. Development patterns by geographic areas varied significantly, and can best be appraised by detailed review of table 6.

TRANSPORTATION

MARINE TRANSPORT

Tankers, bulk carriers, and freighters are the three classes of vessels engaged in transporting mineral commodities. The number, gross tonnage, and deadweight tonnage of these vessels, as reported by the U.S. Maritime Administration for 1973-77, are given in table 7. Although there is a modest difference in reporting categories between 1973-1974 and 1975-77, this difference (inclusion of refrigerated vessels among freighters rather than among other vessels) in the latter period is of little overall significance. It should be noted that vessels in each of the three categories are not wholly devoted to mineral commodity transport. Tankers, although largely engaged in moving crude oil and refinery products, also transport some liquid chemicals, wine, molasses, and whale oil. Bulk carriers move agricultural products as well as crude minerals and mineral fertilizers, while freighters, because of their great variety, can be wholly devoted to hauling mineral products or wholly to moving nonmineral goods, as well as carrying mixed mineral and nonmineral cargos.

Table 8 gives information on total loadings and unloadings of vessels, divided between tanker-type cargo and dry cargo, for the years 1973-77. The foregoing text on trade discussed the disparity in growth rates between the value of mineral commodities moved and total quantity of goods loaded during the years covered by this table. While it is recognized that these figures on loadings and unloadings include goods other than minerals, these nevertheless serve as a reasonable measure of mineral commodity shipments, because of the preponderance of total weight of all goods moved is accounted for by minerals. Some measure of the significance of mineral commodity movement to total commodity movement is apparent in data for the world's two major canals, the Panama and the Suez, and it should be noted that figures for these waterways are skewed in favor of nonmineral commodities by both waterways' inability to handle the huge supertankers and bulk cargo vessels engaged in ore trade. Although exact recent figures are not available, it appears likely that minerals and mineral products account for three quarters or more of total cargo carried in any one year on a weight basis.

A geographic breakdown of loadings and unloadings of dry cargo and tanker cargo are given in tables 9 and 10, respectively, for 1975-77, on a tonnage basis. Again recognizing that both tables include mineral and nonmineral goods, but also recognizing the dominance of mineral materials from the viewpoint of tonnage, these tables give some idea of the relative importance of various world areas as origins and destinations for mineral materials.

Bulk Carriers.—In 1977, the world's bulk carrier fleet increased by 362 vessels, compared with an increase of 298 vessels in 1976. This represented a 7.9% growth in 1977 on the basis of the number of vessels, which can be compared with an 8.7% increase in gross tonnage and a 9.4% increase in deadweight tonnage, demonstrating the continued gradual shift toward larger vessels. In 1977, the average bulk carrier grossed 21,034 tons and had a deadweight tonnage of 36,219, compared with 1976 figures of 20,886 and 35,733 tons, respectively. The following tabulation shows the distribution of the world bulk carrier fleet by country of registry in 1977:

Digitized by Google

Country	Number of vessels	Deadweight tonnage (thousand tons)
Liberia	1,037	44,102
Japan	590	23,688
Greece	691	18,485
Norway	320	17,990
United Kingdom	322	14,643
Italy	158	7,448
Panama	325	7,314
India	103	4,308
Sweden	76	4,269
Germany, Federal Republic of	72	3,920
France	55	2,690
Singapore	67	2,397
U.S.S.R.	178	2,315
Spain	64	2,017
Brazil	42	1,945
Poland	76	1,881
Other	756	19,221
Total	4,932	178,633

Freighters.—In 1977, the world's freighter fleet declined by 747 vessels, but increased in terms of gross tonnage (4.4%) and deadweight tonnage (5%), another reflection of the increase in vessel size aimed at more economical operations. The average freighter in 1977 had a gross weight of 6,686 tons (6,032 tons in 1976) and a deadweight tonnage of 9,022 tons (8,097 tons in 1976), substantial increases when the number of vessels involved is considered. The following tabulation shows the distribution of the world's freighter fleet by country of registry in 1977:

Country	Number of vessels	Deadweight tonnage (thousand tons)
Greece	1,263	11,959
U.S.S.R.	1,727	10,805
Panama	1,414	10,598
United Kingdom	667	6,905
United States	484	6,890
Japan	747	6,431
Liberia	593	6,109
Germany, Federal Republic of	433	3,960
China, People's Republic of	320	3,339
Singapore	373	3,086
Cyprus	422	2,668
Norway	285	2,469
India	214	2,462
Netherlands	330	2,368
Other	3,904	29,808
Total	13,176	109,857

It is noteworthy that Greece displaced the U.S.S.R. as the first-ranked nation in terms of deadweight tonnage.

Tankers.—In 1977, the world's tanker fleet was 50 vessels smaller than in 1976, a decrease of nearly 1%, but the gross tonnage for vessels of this class advanced by 3.5% and the deadweight tonnage by 4.3%. The growth rates for tonnages for tankers were lower than the corresponding figures for bulk carriers and freighters, reflecting the reduced growth rates in world petroleum movement and supply. Nevertheless, the upward trend in the average size of tankers continued, with the average tanker in 1977 grossing 34,766 tons (33,274 tons in 1976) and having a deadweight tonnage of 65,625 tons (62,344 tons in 1976). The following tabulation distributes the world's tanker fleet by country of registry in 1977:

Country	Number of vessels	Deadweight tonnage (thousand tons)
Liberia	982	107,454
Japan	488	32,279
Norway	341	32,033
United Kingdom	375	29,476
Greece	366	19,124
France	144	15,941
Panama	259	13,086
United States	276	12,149
Italy	232	8,959
Spain	130	8,926
U.S.S.R.	465	7,143
Germany, Federal Republic of	80	6,748
Sweden	79	6,485
Singapore	110	6,294
Denmark	73	5,480
Netherlands	72	4,297
Other	861	34,102
Total	5,333	349,976

OCEAN FREIGHT RATES

In general, ocean freight rates turned downward in 1977 from the levels of 1976, according to data published by the United Nations. Rates advanced over 1976 only in the cases of the smallest size groups of vessels, and these upturns were noted both for tanker cargos and dry cargos. For statistical details, the reader is referred to the United Nations Monthly Bulletin of Statistics; indexes of ocean freight rates are published quarterly in March, June, September, and December.

PANAMA AND SUEZ CANALS

The Panama Canal reported a decline in the number of vessel transits but an increase in the quantity of cargo moved through the canal in the fiscal year October 1, 1976, through September 30, 1977, in comparison to the fiscal year July 1, 1975, to June 30, 1976. In fiscal year 1977, mineral commodities constituted about 48% of total cargo moved. The following tabulation summarizes Panama Canal activities for the fiscal years 1975-77, with a separate column for the transition quarter (July-September

Digitized by Google

1976) that resulted from the change in the U.S. Government's fiscal year:

	Fiscal year[1]		Transition quarter[2]	1977
	1975	1976		
Number of transits:				
Commercial ocean traffic	13,609	12,157	3,037	11,896
Other traffic	1,126	1,044	276	1,191
Total	14,735	13,201	3,313	13,087
Cargo moved (thousand metric tons):				
Commercial ocean traffic:				
Mineral commodities	89,250	65,861	15,008	60,078
Other commodities	53,100	53,233	16,376	64,875
Subtotal	142,350	119,094	31,384	124,953
Other traffic	543	193	58	219
Total	142,893	119,287	31,442	125,172

[1]Data for 1975 and 1976 are for years ending June 30 of that stated; data for 1977 are for year ending September 30, 1977.
[2]July 1, 1976-September 30, 1976.

Among major groups of mineral commodities, coal and coke accounted for 21.9% of total mineral commodities in fiscal 1977, followed by crude oil (21.3%), petroleum refinery products (17.1%), metallic ores (16.9%), and fertilizer materials (11.2%). For further details on Panama Canal operations, the reader is referred to the Panama Canal Company Annual Report series.

The Suez Canal recorded an increase in both number of vessel transits and in cargo moved in 1977 with respect to 1976 levels, but the quantity of mineral commodities moved fell sharply, as shown in the following tabulation summarizing operations:

	1975[1]	1976	1977
Number of transits:			
Commercial ocean traffic	5,495	16,402	NA
Other traffic	84	404	NA
Total	5,579	16,806	14,703
Cargo moved, commercial ocean traffic (thousand metric tons):			
Mineral commodities	16,684	105,203	68,806
Other commodities	20,936	12,450	59,887
Total	r37,620	r117,653	128,693

rRevised. NA Not available.
[1]June 5 through December 31.

Major components of total mineral commodity trade were crude oil (35.7%), petroleum refinery products (15.7%), fertilizer materials (10.7%), and cement (8.8%).

It is significant to note that since its reopening, the Suez Canal has been transiting a growing number of the smaller so-called supertankers—200,000 tons and over. These vessels can successfully utilize the canal only in their unladen (generally southbound) trips from the refining centers of Europe and Eastern North America back to the Persian Gulf ports, but even this one-way use of the canal reduces sailing time and distance compared to the journey around the Cape of Good Hope, thereby reducing operating expenses significantly. The largest vessel to transit the canal in 1977 was about 250,000 tons; larger craft cannot use it even sailing in ballast (unladen). Development activities were under way in 1977 aimed at a goal of permitting vessels of up to 150,000 deadweight tons to transit the canal fully laden by June 30,

1980.

PIPELINES

An overall appraisal of worldwide progress on pipelines is impossible owing to limitations of space and time; however, in general terms, construction activity continued at a substantial level. The Trans-Alaskan pipeline linking Alaska's north slope oilfields to the Port of Valdez operated at a rate of over 1 million barrels per day. Gaslines were completed linking Norway's North Sea fields to the main European continent, and shipments began.

PRICES

Comprehensive data on world prices for crude minerals and mineral products are not available, but tables 11, 12, and 13 reflect the mixed pattern in nonferrous metal prices in the United States, the United Kingdom, and Canada, respectively, during each month of 1977. Individual monthly patterns are not consistent between the various markets and defy clear verbalization, but it is evident in comparing annual average figures that aluminum, lead, and tin prices increased in both 1976 and in 1977 over previous levels in each market area; that copper, after increasing between 1975 and 1976, declined in 1977; that silver, after a decline between 1975 and 1976, registered a notable increase in 1977; and that zinc continued downward in 1977 after a decline in 1976 in both the U.S. and United Kingdom markets and a very small 1975-76 increase on the Canadian market.

Regretably, the United Nations statistical series on export price indexes for mineral commodities which appeared in tables 32 and 33 of the 1976 edition of this chapter has been discontinued, and the tables are therefore omitted since nc more recent data are available than those published in the previous edition.

Little need be said about continued advances in fuel prices. Though growth rates varied around the world, the trend was almost without exception upward, with oil leading the way and gas and coal following along, in an upward direction. The requirements of other sectors of the mineral industry for fuels to process crude mine products into ores, made price increases for a number of mineral commodities inevitable and affected industry profitability for commodities that were in oversupply, where fuel prices could not be successfully passed on to nonfuel mineral purchasers.

STATISTICAL SUMMARY OF WORLD PRODUCTION AND TRADE OF MAJOR MINERAL COMMODITIES

The final 24 tables of this chapter (tables 14 through 37) extend the statistical series on production that was started in the 1963 edition of the International Area Reports volume of the Minerals Yearbook and was subsequently updated and expanded in the 1965 and 1967-76 editions. They are primarily a supplement to other statistical data within this chapter but also serve as a summary of international production and trade data for major mineral commodities covered in greater detail on a commodity basis in Volume I of the 1976 Minerals Yearbook and on a country basis in the balance of Volume III.

The data presented in these tables in most instances correspond directly to the data in the individual commodity world production tables appearing in Volume I and as such may not correspond exactly to figures presented in the individual country chapters of Volume III. Such differences are usually the result of the receipt of revised data for inclusion in either a commodity chapter or a country chapter subsequent to the completion of the other chapter. In most cases, country chapters were prepared later than commodity chapters and should be regarded as more reliable. In this 1977 edition, one additional commodity, chromite, has been added to the roster of commodities covered, this because of the relatively large volume of this mineral that is mined and shipped annually, and because of considerable international interest in the commodity.

Data presented in previous editions of this chapter, summarizing world trade in major mineral commodities (see tables 57-69 in the 1976 edition), could not be included in this edition because of other Bureau projects and alterations in the schedule for preparing the Minerals Yearbook.

Refined do.	19,674	21,270	22,387

[p]Preliminary. [r]Revised.

[1]Incorporates numerous revisions from world production tables and country production tables appearing in Volumes I and III, respectively, of the Minerals Yearbook, as well as from the table corresponding to this table in previous editions of this chapter.

[2]Includes bauxite equivalent of nepheline syenite and alunite produced in the U.S.S.R. (the only producer of record of such materials as a source of aluminum).

[3]Excludes data for the United States (withheld to avoid disclosing company proprietary data).

[4]Excludes data for the People's Republic of China (no adequate basis for estimation available).

[5]Excludes data for the U.S.S.R. (no adequate bases for estimation available).

[6]Includes all metal clearly identified as primary as well as all metal that cannot be subdivided clearly between primary and secondary (see footnote 7).

[7]Includes only that metal that is clearly identified as secondary. Some countries do not distinguish between primary and secondary and for some of these, no basis is available for estimating the breakdown of total production. For such countries, the total has been included under primary above (see footnote 6).

[8]Excludes data for the United States (withheld to avoid disclosing company proprietary data), which in previous years accounted for approximately 50% of the world total.

[9]Includes leucoxene and titaniferous slag.

[10]Data are for years ending June 30 of that stated.

[11]Comprises sulfur produced by the Frasch process plus sulfur mined in the elemental state from ores.

[12]Comprises sulfur recovered from coal gasification, metallurgical operations (except pyrite processing), natural gas, petroleum, tar sands, spent oxides, and gypsum, whether recovered in the elemental state or as a sulfur compound.

[13]Production of coke other than metallurgical by the People's Republic of China and the U.S.S.R. included with metallurgical coke production.

Table 2.—Value of world export trade in major mineral commodities[1]

(Million U.S. dollars)

Commodity group	1972	1973	1974	1975	1976	1977
Metals:						
All ores, concentrates, scrap	7,749	10,957	15,608	14,867	15,743	16,010
Iron and steel	20,103	28,464	46,424	45,783	44,661	46,825
Nonferrous metals	11,902	17,301	24,814	18,304	21,423	24,012
Subtotal	39,754	56,722	86,846	78,954	81,827	86,847
Nonmetals, crude only	3,035	3,842	5,758	6,167	6,391	6,962
Mineral fuels	41,775	63,153	172,178	169,281	199,273	221,137
Total	84,564	123,717	264,782	254,402	287,491	314,946
All commodities	413,382	573,788	837,394	872,574	988,947	1,123,624

[1]Data presented are for selected major commodity groups of the Standard International Trade Classification Revised (SITC-R) and as such exclude some mineral commodities classified in that data array together with other (nonmineral) commodities. SITC-R categories included are as follows: All ores, concentrates, and scrap-SITC Division 28; iron and steel-SITC Division 67; nonferrous metals-SITC Division 68; nonmetals (crude only)-SITC Division 27; mineral fuels-SITC Division 3. Major items not included are the metals, metalloids, and metal oxides of SITC Group 513; mineral tar and other coal-, petroleum-, and natural gas-derived crude chemicals of SITC Division 52; manufactured fertilizers of SITC Division 56; and nonmetallic mineral manufactures of SITC Groups 661, 662, 663, 667. Data include special category exports, ships' stores and bunkers and other exports of minor importance, and excludes the intertrade of the centrally planned economy countries of Asia and trade between Federal Republic of Germany and German Democratic Republic.

Table 5.—Annual investment expenditure in the steel industry for selected countries

(Million dollars unless otherwise specified)

Country or country group	1975	1976	1977
EEC	3,302	[1]3,293	[1]2,378
EFTA[2]	475	816	544
Other countries:			
Australia	131	164	140
Canada	238	392	391
Japan	2,033	3,443	3,824
Spain	239	420	476
Turkey	180	271	295
United States	1,400	3,255	2,965
Total	7,998	[3]12,054	[3]11,013

[1]Source reports values for EEC countries are in terms of "million units of account." For the Federal Republic of Germany (included in EEC in this tabulation), the source indicates that for 1976, 823.1 million "units of account" was equivalent to $885.3 million (no conversion rate given for other countries for 1976 and no conversion rate given for any country for 1977, and no further explanation is offered).

[2]Figures exclude data for Switzerland.

[3]Figures have been totaled as if EEC data were U.S. dollars, in keeping within totals appearing in a graph in source publication (see footnote 1).

[1]Maritime Administration classification. Tankers include whaling tankers. Vessels shown here as "Other" include combination passenger and cargo, combination passenger and refrigerated cargo, and refrigerated freighters, except as otherwise indicated. Contribution of these vessels to mineral commodity trade is regarded as unimportant. Data are as of December 31 of year indicated.
[2]Figures include refrigerated freighters.
[3]Figures exclude refrigerated freighters.

[e]Estimate. [p]Preliminary. [r]Revised.

[1]This table includes all recorded production of sulfur, regardless of the form in which it is recovered. Thus, it includes elemental sulfur, whether mined by conventional methods or by the Frasch process, as well as (1) elemental sulfur and the sulfur content of compounds such as H_2S, SO_2, and H_2SO_4 recovered as a principal product of pyrite mining and as a byproduct of the recovery of crude oil and natural gas and as a byproduct of petroleum refining, coal treatment, and metals smelting and/or refining; and (2) sulfur recovered from tar sands, spent oxides, and other miscellaneous sources.

[2]Entirely Frasch-process sulfur.

[3]Includes Frasch-process sulfur as follows, in thousand metric tons: Poland: 1975—4,321, 1976—4,341, 1977—4,405; U.S.S.R. (estimated): 1975—320, 1976—500, 1977—500; total of individually listed countries and grand total: 1975—14,641, 1976—13,870 1977—13,164. The balance is mined elemental sulfur.

[1]In addition to the countries listed, the People's Republic of China may also produce natural gas liquids, but available information is inadequate to make reliable estimates of output levels. Every effort has been made to include in this table only those natural gas liquids produced by natural gas processing plants, and to exclude natural gas liquids obtained from field treatment facilities including wellhead separators, because the latter are normally blended with crude oil and thus are included in crude oil statistics output. In some cases, however, sources do not clearly specify whether data presented represent only output of natural gas processing plants or if they include field output. Thus, some of the figures in this table may include field condensate.

Ocean Minerals

By William T. Cocke[1]

Nickel, copper, cobalt, and manganese are among the minerals found in iron-manganese concretions, or nodules, on the deep sea floor. These small potato-shaped seabed nodules are found in large quantities in areas of the Atlantic, Pacific, and Indian Oceans. Generally black in color, they consist of concentric bands of ferromanganese oxides around nuclei of sharks' teeth, coral, pumice, various forms of silica, and other diverse hard objects found on the seabed. The nodules range in diameter from 0.5 to 20 centimeters or larger.

Seabed nodules are found at ocean depths of generally 2,000 to 6,000 meters and in many types of environments, including seamounts, plateaus, ridges, banks, continental borderlands, and abyssal depths. Concentrations of nodules on the seabed vary widely with location and are as high as 25 kilograms per square meter in some regions. There is also a great variation in the chemical composition of the nodules; percentages of contained nickel, copper, cobalt, manganese, and other metals vary both locally and regionally.

The discovery of these ocean nodules dates back to the 1872-76 voyages of the *HMS Challenger*. Although nodule studies have been going on for 100 years, more intensive interest has taken place since the middle to late 1950's. As early as 1952, seabed nodules were recognized as a potential mineral resource by Dr. John Mero of the Institute of Marine Resources, University of California, and by 1961 he had published chemical compositions of Pacific nodules.

Exploration of seabed nodule deposits has been carried out since 1962. Most studies have been made in the Equatorial North Pacific Ocean, which is believed to contain the most economically feasible concentrations of nodules with high metal content. The high-grade nodules in economic concentrations were found in the pelagic sediments of the Pacific. In the early 1960's, the colloidal or hydrogenous theory of nodule origin was considered.[2] It was believed that seawater, saturated with iron and manganese, precipitates colloidal microparticles that increase in size as they slowly settle to the ocean floor. As they settle, the microparticles attract ions of elements such as nickel, copper, and cobalt, all of which have high electric charge density. These microparticles are then attracted to centers of accretion forming iron- and manganese-rich nodules in areas of low sedimentation, such as the red-clay pelagic zones of the abyssal Pacific. Although nodules may also form by this process in the Atlantic and Indian Oceans, those in these Oceans' areas are generally considered of less importance from an economic standpoint. Other theories of origin have been advanced, and current theories suggest that a number of mechanisms may contribute to the ferromanganese deposition in the form of seabed nodules.[3]

Exploration of the seabed nodule deposits has been accomplished by underwater photographic methods involving both television and still cameras and by bottom-sampling methods utilizing dredges, cores, and grabs. The photographic methods are used to establish concentrations of nodules and areas of extent. The bottom samples are analyzed for metal content and physical size.

The nickel-copper-cobalt content, as well as seabed concentration, is far from uniform. In 1965, Mero published data on this variation of nodule composition in the Pacific.[4] The composition, while locally erratic, shows marked regional trends of enrichment or depletion of the nickel, copper, cobalt, and manganese content, which are not distinct owing to sparsity of data. Delin-

Digitized by Google

eation becomes more defined, however, as more samples are collected.

Industry interest in ocean mining projects was precipitated in 1962 by the announcement that Summa Corp. was to begin seabed nodule exploration aboard the *Glomar Explorer*.[5] In 1968, another Global Marine Development Co. ship, *Glomar Challenger*, began the Deep Sea Drilling Project, under which ocean basins have been drilled to great depths at numerous locations. In the early 1970's, the *R/V Prospector* operated by Deepsea Ventures Inc. (DSV) dredged nodules from the Blake Plateau in the Atlantic Ocean. The West German ship *R/V Valdivia* began working with the *Prospector* and later continued on its own deep ocean mining program.

In 1974, international ocean mining consortia began to form to share the high cost of financing development and testing of ocean mining schemes. At this time, DSV made a claim to the U.S. Department of State for a minesite in the Northeast Pacific.[6]

With the accumulation of more data, seabed nodule resources were estimated for the Northeast Pacific, primarily in the area between the Clarion and Clipperton fracture zones between Hawaii and Baja, Calif. Gross estimates of nodule resources were as high as 1 trillion tons.[7] Other estimates, based on various parameters, ranged from 270 million to 70 billion tons.[8]

It can be inferred from the numerous analyses of nodules in the Northeast Pacific that a typical grade of an economic deposit would average 1.3% nickel, 1.1% copper, 0.25% cobalt, and 25% manganese. The following table shows average grades, in percent, of North Pacific nodules based on various published analyses:

Source and date	Nickel	Copper	Cobalt	Manganese
Mero, 1965	0.99	0.53	0.35	24.2
Cronan, 1972	1.08	.63	.19	22.3
United Nations, 1973	1.28	1.16	.23	24.6
United Nations, 1974	1.6	1.4	.21	24.0
Deepsea Ventures Inc., 1974	1.28	1.07	.25	--
Kennecott Copper Corp., 1975	1.3	1.1	.2	30.0
Metallgesellschaft AG, 1975	1.36	1.2	.2	29.8

Centre National pour l'Exploitation des Oceans (CNEXO), 1977	1.22	1.03	.24	--
Tinsley, 1977	1.3	1.1	.25	29.0

In addition to industry activity, several governments were funding or sponsoring nodule research, exploration, and development. The West German Government was the first to fund substantial nodule exploration and development and has financed much of the activity of Arbeitsgemeinschaft Meerestechnischgewinnbare Rohstoffe (AMR) since 1971.[9] The Japanese Government financed the construction of a marine geological survey vessel and contributed to its operation and to the development of mining and processing systems. The French Government, through Centre National pour l'Exploitation des Oceans (CNEXO), Commissariat à l'Énergie Atomique (CEA), and Bureau de Recherches Géologiques et Minières (BRGM), supported extensive exploration programs, as well as development of mining and processing technology for seabed nodules. The Canadian Government established a marine resources group to monitor the development of seabed nodule mining and to assess its effect on the mineral industry of Canada. The United Kingdom and the U.S.S.R. also sponsored ocean mining research and development.

Agencies of the U.S. Government have administered seabed nodule programs since 1969. The National Oceanic and Atmospheric Administration (NOAA) sponsored environmental studies of nodule mining and processing and monitored major tests of nodule mining systems. Early studies led to the establishment of NOAA's Deep Ocean Mining Environmental Study (DOMES). The potential of nodule mineral resources led the National Science Foundation's Office of International Decade of Ocean Exploration (IDOE) to sponsor a conference, "Ferromanganese Deposits on the Ocean Floor," in January 1972. The geological, economic, legal, environmental, and technical aspects of seabed nodule mineral development were reviewed at the conference.[10] The Ocean Mining Administration (OMA), established in 1975 in the U.S. Department of the Interior, conducted nodule resource assessment and economic analysis of nodule mining. The U.S. Bureau of Mines provided technical support to OMA and conducted research on metallurgical processing and recovery of metals from the nodules.

In addition to the deep ocean mining of

Digitized by Google

nodules in international waters, there has also been interest in offshore mineral resources within Territorial waters. Mineral activities in these areas include dredging of sand and gravel, mining of phosphoritic and barite deposits, installation of sulfur wells (Frasch process), and mining of alluvial and placer deposits (gold, tin, and diamond), iron sands, and metalliferous brines.

LAW OF THE SEA

In 1967, following previous conferences in 1958 and 1960, the U.N. General Assembly created an ad hoc committee of 35 nations to study the question of uses of seabed resources in the interest of mankind. This Seabed Committee met several times from 1969 to 1973 to prepare a draft text of treaty articles to serve as a basis for negotiations for the Third U.N. Conference on Law of the Sea (UNCLOS III). The principle of the common heritage of mankind was first advanced in these articles. This concept was originally construed to eliminate any sovereignty over seabed resources, but interpretations vary on its legal bearing. Some maintain that while the seabed resources belong to everyone, they belong to no individual, and others believe that the principle is not in opposition to high seas rights which means the seabed resources belong to anyone. The U.N. Seabed Committee also proposed three committees for UNCLOS III, based on its three subcommittees. Committee I dealt with matters relating to the seabed. Committee II handled problems relating to navigation through international straits, limits of the territorial sea and exclusive economic zone, the contiguous zone, legal limits of the continental shelf, conservation of living resources, and preferential rights of coastal states. Committee III dealt with matters relating to the marine environment, marine pollution and scientific research, and the right of innocent passage.

The first five sessions of UNCLOS III met with little success. During the Fifth Session in August and September 1976, a deadlock resulted from the position taken by the bloc of developing nations known as the Group of 77. This Group considered the system of exploitation of the seabed set forth in Committee I texts unacceptable and rejected the Revised Single Negotiating Text (RSNT), which had resulted from the previous session and which represented a consensus of a large number of issues before the Conference.

On March 3, 1977, Elliot L. Richardson was appointed by President Carter to serve as Ambassador at Large and Special Representative of the President to UNCLOS III. He replaced T. Vincent Learson as chairman of the U.S. delegation.

The Sixth Session of UNCLOS III was held at U.N. headquarters in New York City from May 23 to July 15, 1977. Based on decisions made at the end of the Fifth Session and during informal consultations held in Geneva earlier in 1977, the entire Conference directed its attention to major seabed mining issues during the first 3 weeks. This work was coordinated by Minister Jens Evensen of Norway, who had led earlier sessions and intersessional consultations on the subject. Successive revised texts were produced for consideration, and the evolution of the Evensen texts suggested that the negotiating process was moving closer to a consensus. However, at the end of the session, Committee I Chairman Paul Engo of Cameroon, rather than submitting the Evensen compromise formula, submitted his own versions as the Committee I text of the Informal Composite Negotiating Text (ICNT). Coming unilaterally and not from negotiations, the Engo texts upset the balance achieved by Evensen and were considered "fundamentally unacceptable to the U.S." by Ambassador Richardson and the U.S. delegation.[11] The substantive difficulties were that the United States was not given reasonable assurance of access to minesites and that technology transfer and joint ventures with the International Seabed Authority (ISA) were conditions of access. The United States had agreed earlier to the RSNT, a compromise proposal, for financing the ISA through a partial or dual system of exploitation that would allow access to State and private operators in addition to the Enterprise, the operating arm of the ISA. Other problems with the ICNT were absence of reasonable limits on financial burdens (revenue sharing), production limitations more stringent than necessary to protect producers from specific countries, unacceptable power given to the ISA to regulate all other seabed mineral production, distribution of benefits to countries not party to the Conference, and, unless agreement to the contrary was

Digitized by Google

reached within 25 years, automatic conversion of the regime into a unitary system blocking direct access to all but the ISA, except by its consent.

The ICNT was considered by the U.S. delegation to be further from an acceptable compromise than the RSNT derived from the previous session.

U.S. DEEP SEABED MINING LEGISLATION

Since November 2, 1971, when Senator Metcalf of Montana introduced S. 2801, there has been a succession of bills in both houses of Congress to provide authority for the development of the hard mineral resources of the deep seabed. S. 2801 was an outgrowth of a series of hearings before the Special Subcommittee on the Outer Continental Shelf of the Senate Committee on Interior and Insular Affairs. Testimony indicated that U.S. industry was nearing mining capability and that domestic legislation was needed.

Various proposed bills outlined the establishment of a regulatory system to promote the orderly development of deep seabed hard minerals. They included provisions for exploration licenses and permits for commercial exploitation. Enforcement procedures for protection of the marine environment in accordance with established criteria and standards relating to environmental impact statements were also proposed. The proposed bills were to be interim in nature, pending the establishment of an international regulatory regime resulting from UNCLOS III or another multinational treaty.

On February 9, 1977, Representatives John Murphy of New York and John Breaux of Louisiana introduced H.R. 3350, which was referred jointly to the House Committee on Merchant Marine and Fisheries and the House Committee on Interior and Insular Affairs. Hearings were held in March, April, and May before the Subcommittee on Oceanography of the House Committee on Merchant Marine and Fisheries, and the bill was reported from the Committee with amendments on August 9, 1977. On November 7, 1977, H.R. 3350 was reported from the House Committee on Interior and Insular Affairs with amendments and referred to the House Committee on International Relations for a period ending February 10, 1978.

On August 5, 1977, Senator Metcalf introduced S. 2053, which was referred jointly to the Senate Committee on Commerce, Science, and Transportation and the Senate Committee on Energy and Natural Resources. Joint hearings were held in September.

The Administration announced support of seabed mining legislation following the close of the Sixth Session of UNCLOS III. However, it opposed the provision in both bills calling for U.S. investment guarantees covering industry losses stemming from an unfavorable Law of the Sea treaty. In lieu of such guarantees in domestic legislation, the Administration favored a "grandfather rights" clause in the prospective UNCLOS III treaty.

OCEAN MINING CONSORTIA

As early as 1962, industry interest in ocean mining had developed to the point where Kennecott Copper Corp. and Tenneco Inc. were funding projects. From 1962 to 1968, efforts were confined primarily to mineral resource research, data collection, mining system design, economic feasibility studies, and bench-scale process testing.

During the period 1969-74, preliminary engineering development of deep seabed mining systems was underway. Companies active during this period were Kennecott, DSV, Lockheed Missiles and Space Co., Inco Ltd. (Canada), Metallgesellschaft AG (Federal Republic of Germany), CNEXO (France), and several Japanese companies.

In late 1974, major organizational changes took place among operating companies during a period of demonstrating feasibility by trial mining and processing. Because of the high capital costs involved, international mining consortia were formed to finance these endeavors. Since 1975, the industry has been involved in the study of the technological and economic feasibility of ocean mining, trial mining tests, and demonstration of pilot processing plants. Table 1 shows the structure of the various major international consortia.

Kennecott Consortium.—The Kennecott Consortium was the first international consortium formed to investigate the recovery and processing of seabed nodules. It was formalized in January 1974 to undertake a 5-year program of study.[12] Kennecott Exploration Inc. was to manage this unincorporated joint venture. Marne A. Dubs was director of Kennecott's Ocean Resources Group, part of the Corporate Exploration Group. Seagoing operations were centered in the Ocean Operating Division, which was formed in 1962. This division sponsored exploratory cruises before putting to sea itself in 1967. Kennecott was an early proponent of free-fall sampling devices. In 1970, a 5-ton dredge bucket was used to recover 50 tons of nodules from 4,600-meter depths.[13] The company was also active in box-core sampling and seafloor photography. Two large areas in the Pacific Ocean that showed favorable mineral abundance and grade were located and explored.[14]

A 2,000-ton-per-day nodule-collecting device, towed by cable, was tested at 4,600-meter depths in the Pacific.[15] In 1976, a test (1/10 of commercial scale) was made to depths of 5,000 meters. Although no nodules were recovered, as the recovery pipestring was not tested, the device demonstrated efficiency for nodule recovery, with collection of 90% of available nodules in the path of the mining device. Kennecott favored an inline hydraulic system, employing a 50-centimeter-diameter pipe capable of mining 5,000 to 15,000 tons per day or 3 million tons per year.[16] Initial large-scale tests (1/3 to 1/2 scale), scheduled for 1977, were postponed until 1978, reportedly owing to the prevailing weak metal market and lack of progress in UNCLOS III. A mid-1978 test of inline submerged hydraulic pumps was ex-

Digitized by Google

pected, with full-scale integrated testing by 1979 of a towed dredge at the end of a nearly vertical pipestring.[17] Presumably, a modified drillship or other ship conversion would be used, but no announcement was made concerning vessel selection. Kennecott was also reportedly working on self-propelled sea-bottom nodule collectors.

Kennecott conducted extensive nodule-processing tests at its Ledgemont Laboratory in Lexington, Mass. In 1973, a 0.5-ton-per-day pilot processing plant was operated, and by early 1974 Kennecott had essentially finished nodule-processing research. Kennecott has developed several unique hydrometallurgical techniques; the ammonia-based "cuprous ion" (Cuprion) metal extraction process was preferred. Recovery was claimed to be 90% for nickel, 92% for copper, and 85% for cobalt. Kennecott also considered recovery of incremental amounts of manganese from the Cuprion process tailings, depending on market conditions.[18]

Ocean Management Inc. (OMI).—This group was formalized in April 1975 and embarked on a 4-year study program budgeted at $33 million. John L. Shaw was president of OMI, which had the management contract for the consortium. Each of the members had considerable experience in ocean mining and related technology. Most had been participants in the Continuous Line Bucket Group. Sedco Inc., which joined the group in November 1975, began ocean mining studies in 1966. Inco began investigation of seabed nodules in the early 1960's, concentrating on resource assessment, but did little exploration on its own. Most of the exploration data was from the West German AMR Group, which used the *R/V Valdivia*, a 1,980-ton stern trawler modified in 1970. AMR was founded in 1972 for deep ocean exploration, mining, and processing and to expand on the survey work conducted by Metallgesellschaft. AMR identified several minesites in the Northeast Pacific that OMI considered suitable for ocean mining.

Some sophisticated mining methods were suggested and developed by AMR. Models of collector devices were suggested by the four partners. No lift technique was decided upon, but Inco was apparently planning tests of pump and/or airlift hydraulic systems. OMI planned to use a random technique of mining, keeping the mining ship headed into the wind, possibly cutting fuel costs compared with a regular sweep pattern. Sedco would furnish the mining ship, the 17,000-ton *Sedco 445*, which was converted in October 1977. Dynamic position control was maintained by 11 thrusters, fore and aft. The center well was 21 meters by 11 meters, and the lifting capacity was 680 tons. Initial tests began in November 1977 with plans to mine 5,000 tons of nodules. Airlift injections were to be made at a depth of 1,500 to 2,500 meters, and submersible pumps were placed at about 900 meters. The 24-centimeter-diameter pipestring was to be 5,200 meters long. A patented Inco dredge was to be tested at 1,000 to 2,000 tons per day during a 4- to 5-month test in 1978. Scheduled completion of testing was 1979. Two separate towed mining systems were being used.[19]

Inco conducted various nodule-processing tests, with smelting to matte emerging as the preferred technique, yielding nickel, copper, cobalt, and a ferromanganese product. The reduced metals are contained in an alloy concentrate that can be processed in Inco's existing plants. Sumitomo Metal Mining Co., Ltd., an important participant in Deep Ocean Mining Co. (DOMCO), announced the start of construction of a nodule-processing plant beginning early in 1978.[20]

AMR made investigations including solvent extraction, sulfuric acid leach, and SO_2 roast-leach. The *R/V Valdivia* conducted tests of nuclear-power equipment off Hawaii in 1977.[21] In situ analysis of the mineral content of nodules on the seabed was made.

Ocean Mining Associates (OMA).—This group, as existing in 1977, was formalized in March 1977. The original consortium was formed in May 1974 and included Tenneco, Japan Manganese Nodule Development Co., Ltd., United States Steel Corp., and Union Minière S.A. The Japanese participation was replaced by Sun Co. Inc. in 1975, and Tenneco was replaced by its former subsidiary, DSV. DSV was given a service management contract and has conducted extensive ocean nodule exploration since 1962 — first as Newport News Shipbuilding & Dry Dock Co., a subsidiary of Tenneco; after 1968 as a new subsidiary, Deepsea Ventures; and most recently as DSV.

In 1969, DSV bench-tested an airlift nodule recovery system. Much of its original exploration and testing took place on the Blake Plateau in the Atlantic Ocean, off the Southeastern United States.[22] In 1970, a mining test of the airlift system was con-

Digitized by Google

ducted there at 900 meters. Nodules were successfully brought to the surface through a 24-centimeter- diameter pipestring.

Since August 1969, DSV had conducted a number of detailed exploration cruises in the Northeast Pacific at approximately 15° N., 120° W. Based on these studies, on November 14, 1974, the company filed with the U.S. Department of State a notice of discovery, claim of exclusive mining rights, and request for diplomatic protection of investment. This mining right claim was not officially recognized by the United States or any other country, although in its official reply, the State Department recognized the rights of freedom of the high seas existing under international law.

By 1975, *R/V Prospector*, operated by DSV, had completed 40 exploratory cruises in the Pacific Ocean, with extensive seafloor photography and bottom sampling, and had recovered 300 tons of nodules.[23] Mining tests were conducted from a 98-meter, 7,500-ton converted general cargo ship, the *R/V Deepsea Miner*, which was equipped with a 6.1- by 9.1-meter center well and a 23-meter derrick.[24] As part of DSV's expanded development program, which included pilot-scale mining, the 170-meter, 26,000-ton iron ore carrier *Weser Ore* was converted in Galveston, Tex., in late 1976 and early 1977 and became *R/V Deepsea Miner II*. It is equipped with thrusters, an 8.2- by 10.2-meter center well, and a gimballed platform with 450-ton capacity.[25] A 21-meter-high geodesic dome structure provided weather protection to the 17-meter derrick.[26]

Final debugging of *R/V Deepsea Miner II* took place in February and March 1977 in preparation for test recovery of nodules from 4,600 meters at DSV's Pacific "claim."[27] The tests, covering a 6- to 8-month period, were to be of a 1/5-scale (600-ton-per-day) airlift system. Plans called for recovery of approximately 15,000 tons of nodules to feed a nodule-processing plant for test metal extraction.[28] The dredgeheads were to be lowered over the side and keelhauled under the center well for attachment to the pipestring. Some pipestring problems were encountered initially, but on the second cruise late in 1977 the test of the prototype airlift system was reportedly successful. It was the first time an airlift system had been operated at this depth.[29] The goals achieved were lowering the pipestring to 4,800 meters and demonstrating water circulation capabilities in the pipeline, and lowering the collector to the seabed to determine its ability to track the ship and pipestring. Owing to electrical problems, however, the two systems were not tested together successfully, and therefore no nodules were pumped. The test results were additionally encouraging owing to the difficult weather in which the tests were conducted. All of the tests were monitored for the DOMES project.[30]

OMA had developed three viable hydrometallurgical methods of nodule processing by 1975 through research by DSV, United States Steel, and Union Minière. DSV's process relied on hydrochloric acid leaching developed at Glouchester Point, Va. In 1968, after initial bench testing, a 1-ton-per-day pilot plant was successfully operated. The choice of the chloride process committed DSV to manganese recovery to recycle the chloride ion. Owing to the symbiotic relationship with chlorinated hydrocarbon plants, a nodule-processing plant utilizing the hydrochloric acid leach process could be located in the gulf coast region. OMA, however, may abandon the chloride process owing to high capital costs caused by environmental restrictions.[31] This would mean that the research by United States Steel and Union Minière may become more important. OMA remained interested in a 4-metal recovery, whether employing a hydrometallurgical or pyrometallurgical process. If the chloride process were, in fact, dropped, a planned processing plant could be located on the west coast or Hawaii instead of the gulf coast.

Ocean Minerals Co. (OMINCO).—The Lockheed consortium was formalized in November 1977. James G. Wenzel, Lockheed's vice president for ocean systems, was chairman and president of the venture. Lockheed was engaged as the prime contractor for OMINCO. Lockheed had sponsored ocean mining projects since early 1964 and had sought partners since 1975. In 1974, Lockheed was the main subcontractor for the technical aspects of the venture involving Summa Corp. and the *Glomar Explorer* used to recover parts of a sunken Soviet submarine. Several charters were undertaken in the early 1970's, one of which was a joint venture with the U.S. Bureau of Mines and International Minerals and Chemicals in 1971, to develop ocean-mining systems.[32] Research was directed toward nodule recovery equipment; little deep seabed exploration was conducted.

OMINCO contracted with Global Marine for use of the *Glomar Explorer* for prototype

Digitized by Google

nodule mining tests beginning in 1978.[33] The *Glomar Explorer*, on a 13-month lease to Global Marine, had a lifting capacity nearly 18 times that of most offshore oil-drilling ships. The working payload was 4,000 tons with a 5,200-meter pipestring. The 188-meter, 63,000-ton ship had a center well measuring 61 meters long, 23 meters wide, and 20 meters deep.[34] The lift rate was about 3 centimeters per second, and it would require 3 1/2 days to deploy the pipestring to its full 5,200-meter length. Initial test operations of a 1/5- to 1/4-commercial-scale (1,000-ton-per-day) miner were planned for middle to late 1978. Previous scaled-down tests had been conducted under simulated conditions. Lockheed kept its options on airlift or hydrolift systems. Buoyant submersible lifting was ruled out.[35]

Although little information exists concerning OMINCO's nodule-processing achievements, Lockheed had verified laboratory results of metal product recovery from nodules in a mini-pilot plant operation.[36]

Continuous Line Bucket Group (CLB).—This group was the first of the nodule mine development consortia. It was initially organized in 1971 by Ocean Resources Inc. to develop a CLB mining system and did not intend to enter commercialization, although members were free to proceed with their own plans. John Mero was the project manager for the group and the leading proponent of the system.[37] The system consisted of a continuous line of buckets secured to polypropylene line which was lowered to the bottom, dragged across the seafloor dredging nodules, raised to the surface, and emptied before continuing down again. A full-scale test was conducted at a depth of 4,700 meters.[38] When first tested in 1970 using one ship, efforts were less successful owing to fouling of the up-line and down-line buckets. Other tests were conducted in 1972, 1973, and 1975. A hydrodynamic separation of the buckets has apparently worked well in tests by the Japanese.

The French CNEXO, a leader in technical developments for CLB through computer studies, bucket design, and scale-model testing, proposed a two-ship method which offered greater flexibility in controlling fouling and improved the mining pattern.[39] The two-ship method, tested by CNEXO, employed a lead ship to guide the down-line buckets and control the mining pattern and a mining vessel that hauled the line up and emptied the buckets. CLB was preparing for a test of the two-ship method in 1978,[40] utilizing 16,000 meters of 2,000-ton test polypropylene cable. The mining rate possible was 10,000 tons per day at a loop speed of 1 meter per second.[41]

Association Française pour l'Étude et la Recherche des Nodules (AFERNOD).—This French group had been conducting nodule exploration since 1970. Four original partners spent $20 million since 1970 and entered into a 3-year contract in 1974.[42] Heavy emphasis was placed on minesite delineation. The nodule mining program was formalized in mid-1977, when a fifth member, BRGM, was added to the group. CNEXO, the leader of this group, conducted its research work through contracts with French companies. Early nodule exploration from 1971 to 1974, near Tahiti, was discontinued in favor of the Clarion-Clipperton zone in the Northeast Pacific. The group developed a grid sampling system and delineated several potential minesites in the prime nodule zone.[43]

A mining system was not chosen, but three were being investigated. CNEXO participated in the 1972 CLB test and led in CLB development, especially in the two-ship format. CEA was leading the airlift system effort and developed a final design for sea trials.[44] The group was also considering a hydraulic lift system of a two-stage design in which the nodules are hydraulically lifted by a submerged pump at about a 400-meter depth where the nodules are separated and then pumped to the surface in a concentrated slurry by a second pump.

Processing research was on a bench scale. Both pyrometallurgical and hydrometallurgical processes were considered, with special attention given to sulfuric acid and ammoniacal leaching. CEA investigated the Caron laterite process (ammonia leach) and installed a nodule-processing pilot plant. Soc. le Nickel (SLN) had pyrometallurgical experience with nickel laterites.

Deep Ocean Minerals Association (DOMA).—DOMA, established in 1974, was a Japanese Government-sponsored organization comprising some 30 private Japanese companies under contract to the Metal Mining Agency of Japan, which is part of the Japanese Ministry of International Trade and Industry.[45] DOMA's surveys of the North Pacific nodule area were in conjunction with the Geological Survey of Japan (GSJ), with which it shared the survey ship *R/V Hakurei Maru*. Although

Digitized by Google

GSJ published cruise data reports, little was known of the activities of DOMA. The Japanese Government planned to fund the construction of a second survey vessel by 1980.

Although a Japanese engineer invented the CLB system, the Japanese did not conduct much CLB development since the 1972 test.[46] DOMA was believed to be working on a hydraulic lift system. Mining test work was scheduled for completion in 1979.

Little was known of the nodule-processing plans of DOMA, although the Sumitomo group, one of the member companies, conducted smelting tests on nodule samples.

The Mineral Industry of Afghanistan

By E. Shekarchi[1]

The status of the Afghan mineral industry during 1977 remained almost unchanged from that of 1976. The nation's major mineral production continued to be natural gas from Shibarghan Province. The value of the gross national product (GNP) increased from $2.4 billion[2] in 1976 to $2.5 billion during 1977. These increases were owing to unrecorded remittances, about $50 million brought into the country by a large number of Afghanis working abroad in Iran and other Organization of Petroleum Exporting Countries (OPEC) countries, and a substantial reexport trade with Pakistan and Iran.

A report published by the Ministry of Mines and Industries and the Geological Survey indicated a number of locations and regions where uraium had been found. The report, which was a compilation of the old findings and a new geophysical survey, recommended further detailed geophysical work to outline promising anomalies at the Jalalabad Basin, the Panjshir-Bannyan fault zone, and the Doah- Ishpushtu area.

A report by the United Nations Development Program and the Government of Afghanistan was released at the end of 1977. The report, covering 1977-82, the 6-year period that coincides with the time frame of the Afghan 7-year plan, proposed 11 projects at a cost of $44 million. Of this, only $14 million was for the mining sector.

A report prepared by Soc. Francçaise d'Eétudes et de Realisations Furoviaire (Soferail) recommended a railroad system for Afghanistan, 1,190 kilometers long and costing approximately $1.1 billion, as a part of the 7-year development plan. Construction of the railroad was to begin by the end of 1978 if the Government could obtain enough loans abroad.

Afghanistan completed 2 years of its ambitious 7-year (1977-82) economic and social development plan, which calls for public-sector expenditures for industry, irrigation, and transportation. The largest development projects in the plan were directed toward exploration and exploitation of oil and gas, development of an iron and steel industry to exploit the rich iron ore deposits, and conctruction of a copper smelter to exploit the copper reserves near Kabul. The Government experienced difficulty in attracting foreign investors to take part in these ventures, possibly because the Afghan investment law enacted in 1976 limits foreign ownership of industries to 49%.

Digitized by Google

PRODUCTION AND TRADE

Barite production form the Sanuglan District of Meral Province increased slightly, and exploration work at Faranujal near Ghorband showed proven reserves of 1.5 million tons. Asbestos production reportedly dropped from 13,260 tons in 1976 to 4,500 tons in 1977; however, it is reported that with better transportation facilities the mine could double its production. Afghanistan led in world production of lapis lazuli in 1977 with about 8 tons, which accounted for 80% of world production. Most of the lapis lazuli, a semiprecious gem stone, was exported. The Government intensified its exploration efforts on the Hajigak iron deposits, situated in the Hindu Kush mountains northwest of Kabul. A railroad branch was scheduled to connect this deposit to the main highway system of the country. Proven reserves were reported at 2 billion tons of high-grade iron ore. Exploration for copper continued, and by yearend, 3.5 million tons of copper reserves containing 0.7% to 1.2% copper was proved.

Natural gas production during 1977 amounted to nearly 2.6 billion cubic meters, down from the peak of nearly 3.2 billion cubic meters in 1974. Natural gas production was from 33 wells in the Khawaga Gogerdak gasfield located in Shiberghan Province. Gas was extracted from the upper (1,800-meter) horizons, where recoverable reserves were placed at 23 billion cubic meters of sweet gas. Another 18 billion cubic meters of sour gas, also recoverable, was reported at the lower (2,200-meter) horizon. Gas was collected at two receiving stations and piped to a nearby drying plant. From there, about 95% was exported to the U.S.S.R. tjrpigj a 100-kilometer-long, 820-millimeter-diameter pipeline. Except for a small amount of gas consumed at the drying plant to generate electricity and produce steam, the unexported gas was transported 88 kilometers through a 320-millimeter-diameter pipeline to the Mazar-i-Sharif power and fertilizer plants. Most of the electricity from this powerplant, located within the fertilizer complx, was consumed at the site, with small amounts supplied to the towns of Mazar-i-Sharif and Balkh.

The secon major gasfield under development was Jarq-aduq, about 11 kilometers to the southwest in Shiberghan Province. Production was to begin in 3 or 4 years upon completion of a desulfurization plant that was under construction during 1977. A total of 44 production wells have been planned for this field, along with two pipelines a 30-kilometer-long, 720-millimeter-diameter line for transporting desulfurized gas for export and an 11-kilometer-long, 159-millimeter diameter line to Shiberghan for industrial and consumer uses. The entire project was on a turnkey basis provided by the Soviet firms Technoexport and Mitprom Export.

Recoverable gas reserves of 35 billion cubic meters in the Juma structure northwest of Shiberghan and 12 billion cubic meters in the Atimtag structure near Khawaja were also established. A total of 77 structures were identified by the end of 1977, of which 34 were tested by one or more wells.

Petroleum was discovered in Afghanistan in 1956 at Angut, but it was not until 1970 that the potential of this field was known. Subsequently, in the same general area, three other oil structure— Agdarya, Bazarkami, and Oashg-oir, with total recoverable reserves of about 13 million tons—have been identified. Three discovery wells and one dry well had been drilled by the end of 1977, and two more were underway.

As a result of additional petroleum discoveries, the Government, for the second time, revised upward its refinery requirements to 500,000 tons. In 1977, Afghanistan imported 245,000 tons of petroleum products, vaued at $30 million, compared with 241,000 tons valued at $27 million in 1976. The U.S.S.R. and Iran were its chief suppliers both years.

Table 1.—Afghanistan: Production of mineral commodities

(Metric tons, unless otherwise specified)

Commodity[1]	1975	1976	1977[p]
Asbestos	--	13,260	[e]4,500
Barite	5,200	5,316	[e]5,400
Cement, hydraulic	140,000	[e]167,000	136,201
Coal, bituminous	160,000	164,131	182,000
Gas, natural:			
Gross ---- million cubic feet	105,944	[e]96,000	[e]90,000
Marketed ---- do	98,881	89,805	[e]84,000
Gem stones: Lapis lazuli ---- kilograms	[r]8,108	7,406	6,310
Natural gas liquids ---- thousand 42-gallon barrels	[e]15	9	[e]10
Salt, rock	60,000	69,583	77,684
Talc	6,300	8,685	[e]9,000

[e] Estimate. [p] Preliminary. [r] Revised.

[1] In addition to the commodities listed, a variety of crude construction materials (clays, stone, and sand and gravel) presumably were also produced, but output is not reported and available information is inadequate to make reliable estimates of output levels.

The Mineral Industry of Albania

By George Rabchevsky[1]

In 1977, Albania continued its position as one of the world's largest producers of chromite. According to their claims, Albania also ranks among the principal countries of Europe in reserves of nickel and iron-nickel ores. Chrome ore is Albania's most important export commodity.[2] The country is self-sufficient in energy and exports oil, coal, and electrical energy. Endemic to Albania are vast deposits of natural bitumen, which it utilizes domestically and exports to Yugoslavia. Almost all of the country's iron ore is smelted domestically and many other commodities are retained for local utilization as part of Albania's principle of self-reliance and self-sufficiency.

Even though Albania's fifth 5-year plan (1971-75) fell short of many of its objectives, the current sixth 5-year plan (1976-80) seems to be progressing as planned during its first 2 years. In 1977, however, Chinese-Albanian relations worsened. Because Mainland China has been a principal trading partner of Albania since 1970, and a joint long-term trade and economic agreement granted Albania interest-free loans and technical assistance, the worsening relations, therefore, will undoubtedly affect Albania's domestic and foreign economy in the immediate future.

Government Policies and Programs.—The Albanian sixth 5-year plan envisages a rise of 41% to 44% in industrial production, primarily in the mining industry sector. Priority in 1977 in the country's industrial development was given to the mining and mineral processing industries. The Albanian national plan and budget for 1978 includes a provision for the construction of iron-nickel mines in Prrenjas and Guri-i-Kuq, and in particular to several chromite and copper mines and dressing plants in the districts of Dibër, Mirditë, Korcë, and Kukës. Work will also commence on the construction of another powerplant on the Drin River and the Kaman hydroelectric plant.[3] It is expected that coal, oil and gas, steel, and electric production will also be increased in 1978. Overall industrial production in Albania is scheduled to increase by 8.5% in 1978, over the 1977 target. Because of some failures in 1977, however, the fourth plenum of the Albanian Workers Party Central Committee, which discussed the fulfillment of the 1977 plan and the tasks for the 1978 plan, called not only for the fulfillment of the 1978 plan but also for the compensation of a considerable portion of the deficits created in certain sectors in the previous 2 years. The national income is to increase 12%, a 28% rise in farm production and a 10% increase in exports are also planned for 1978. The volume of capital investment and construction is forecast to increase by 18%, which will include 37 new industrial construction-assembly projects. Work will be continued on the three turbines at Fierzë hydroelectric power station, on the oil refinery and processing plant in Ballësh, and on the Prrenjas-Guri-i-Kuq railway (linking the two iron-nickel mines), and the Fier-Vlora railway. The 1978 state budget set the incomes at lek7,800 million and expenditures at lek7,700 million.[4]

The immediate goal of Albanian geologists is the discovery of new raw materials, such as coking coal, nickel-free iron, phosphates, high-quality asbestos, and many other minerals, more than 40 of which are known to exist in Albania. Over a dozen new mines are planned to be developed during the current 5-year plan and production of chromium ore is to be increased by

Digitized by Google

47%, that of copper ore by 55%, iron-nickel by three times, and coal by two times in relation to the past 5-year plan.[5]

In the current 5-year plan, the Albanian geological survey planned for 66% more drilling, 23% more mine workings, and 26% more of other related work. The economic growth of Albania is closely linked with the development of its mineral resources. The mineral industry is centrally controlled and headed by the Ministry of Heavy Industry and Mining, production schedules and targets are prescribed by the 5-year and annual plans.

PRODUCTION

According to Albanian sources, the 1977 production plan for chromite was exceeded and the plans for copper, iron-nickel ore, and other minerals were fulfilled. The coke and chemical plant of the Elbasan metallurgical complex began production of sulfur in 1977, and the chemical industry in general developed rapidly, using many locally available minerals. Plants were under construction to manufacture fertilizers and pesticides, caustic soda and soda ash, sulfuric acid, and oxygen. Some type of pyrometallurgical plant was also supposedly under construction in 1977.[6]

According to Thanas Dede, Director of Heavy Industry of the Ministry of Heavy Industry and Mining, the plans for the first 2 years of the sixth 5-year plan were fulfilled and surpassed. Special mention was made of the chromite mines in Bulgiza and Batra, the copper mines in Kurbnesh, and the mine construction enterprise. Some mines, however, fell short of the expected plan, such as the coal mines in Tirana and Memaliaj and the chromite and copper mines of Kukës and Korcë. Those mines were the least productive in spite of the repeated recommendations by Government directives to improve their work. The Tirana coal mines were the least progressive in the fulfillment of their plan, with the worst results being in the Mushqeta mine. Lack of personnel and experienced specialists were reportedly the cause of this deficiency, as was the inadequate supply of timber for mine support. As an example of efficient mining practice in areas where timber is scarce, the excavation work in the unstable underground coal formations at Valias was commended, as was work at Gurakup and drilling at Prrenjas and Kalimash. The chromite mines in the Kukës district (Gjegjan, Kalimash, and Thirre) ended the 1977 year with a substantial deficiency, especially in the ore drilling program. Although the industrial quotas have been filled, the mine management has been criticized for not worrying about other production indicators, such as more efficient monitoring of work and the discouragement of the liberal work attitude. Accordingly, the executive committees of the people's councils of Kukës and Mirditë districts (copper and chromite mines) were advised to take measures to supplement the existing labor force, especially in the chromite mines of Kalimash and Thirre. The iron-nickel mine of Cervenaka has, in general, overfulfilled its plan. This mine did not fulfill its 1976 plan and mine managers were accused of remaining indifferent and inactive in their corrective measures. An urgent analysis was proposed for the solution of the materials supply in that district and of the mine management in general. The 1 and 2 coal mines of the Mborje-Drenova district were commended for completing their work and in the overfulfillment of the plan and were cited as an example to the coal mines of the Kolonje district. The Krosnisht, and especially the Bezhan mines of that district, did not meet the plan and the leadership of the Mborje-Drenova mine was instructed to supply the Bezhan mine with mature and experienced miners and specialists for more efficient running of the new mine. Overall production deficiencies and management weaknesses were blamed on the poor performance by the Ministry of Heavy Industry and Mining itself, whose responsibility it was to exert greater control and supervision in the fulfillment of the projected plans.[7]

Rahman Hanku, Minister of the Construction Ministry, reported that in 1977 the industry completed construction and installation of many projects, among them the copper plant in Fushe-Arrez, the quartzite plant in Laç, the Enver machine plant, the iron-nickel mine in Prrenjas, and will soon put into operation the first unit of the hydroelectric plant in Fierzë. Some of those projects, however, have not been totally completed and will be continued in 1978.[8]

The oil and gas industry fulfilled its 1977 plan with the discovery of new reserves and the drilling of a number of oil wells. The Ministry of Heavy Industry and Mining reported, however, that during 1977 many

Digitized by Google

drilling rigs, did not operate at all; furthermore, a number of rigs were left idle due to frequent breakdowns, workers' absenteeism, and poor performance. In 1977, 21% of the workers failed to fulfill their work norms, while 30% exceeded them by over 10%.[9]

Available information on Albania's mineral industry is scant and mostly inferential. Official Albanian production and trade statistics are not available and because entry into the country is strictly controlled, accounts by unofficial and foreign sources are poor and incomplete. Statistical information on Albania has been published by the Federal Bureau of Mines since 1963, and probably the first known account of chrome mining in Albania was published in 1970.[10] Official plans and plan fulfillments, however, are available from Albanian newspapers and media, even though they contain more rhetoric than statistical and factual data. All of the published information is confined to general statements, with percentage figures referring to the degree national plans have been executed. Most of the production data and trade statistics in this report are assimilated from various sources and are compiled from returns, when available, of trading partner countries.

Table 1.—Albania: Production of mineral commodities

(Metric tons unless otherwise specified)

Commodity[1]	1975	1976	1977[p]
METALS			
Chromium, chromite, gross weight thousand tons	779	830	880
Copper:			
Mine output, metal content	[r]9,000	10,000	9,000

[e]Estimate. [p]Preliminary. [r]Revised. NA Not available.

[1]In addition to the commodities listed, a variety of crude construction materials (common clay, sand and gravel, and stone) is undoubtedly produced, but output is not reported quantitatively and available information is inadequate to make reliable estimates of output levels. Moreover, metallic nickel production reportedly began in 1978, but no data on the level of production is available.

[2]Data on petroleum refinery-produced asphalt and bitumen are included with natural asphalt and bitumen.

[3]Separate data on marketable production are not available, but gross and marketed output are regarded as nearly equal.

[4]Estimates based on estimated tonnages published by the United Nations in World Energy Supplies 1972-76. Statistical Papers, Series J, No. 21, New York, 1978, 233 pp.

[5]Partial figure, sum of listed products only, no estimates have been made for other products produced.

TRADE

In 1977, Albania continued to practice its policy of self-reliance and economic self-sufficiency. Albanian relations with Mainland China, its principal trading partner, worsened in 1977, and Albania began to look into expanding its exports elsewhere to pay for increasing imports. According to various sources, in 1977 Albania had economic and diplomatic relationship with about 80 countries.[11]

Minerals and related products, as in previous years, accounted for most (75%) of Albania's exports in 1977, while it imported heavy machinery, technology, and consumer goods.

Chromite continued to be Albania's most important export commodity. Of the estimated 880,000 tons of chromite preduced in 1977, 720,000 tons or 82% was exported. Other important Albanian exports included natural bitumen, oil, iron-nickel ore, copper, and hydroelectric power. All of the exported hydroelectric power was sent to northern Greece and Yugoslavia.

In 1977, in addition to the consumer goods and heavy machinery, Albania continued to import pig iron and steel products, coke, and fertilizer materials. In general, however, the domestic supply of raw materials is sufficient for the country's present low-level industrial development and, therefore, the requirements for imports of raw materials are kept low. China was not only Albania's trading partner in 1977, as in previous years, but also was its technical ally, as technical and economic assistance of China dominated the Albanian economy. Both, the Elbasan ferrous metallurgical complex, Albania's largest, and the oil refinery at Ballesh, the second largest plant, were built with Chinese assistance.

In 1977, however, Chinese-Albanian relations began to deteriorate, as Albania criticized certain aspects of Chinese foreign policy after Mao Tse Tung's death. Long-term trade and economic agreements between the two countries resulted in Chinese participation in the industrialization of Albania, the latter becoming China's only ally. By 1976, 54% of Albanian chrome ore, for example, was shipped to China, which accounted for nearly the total Chinese chrome requirements.

Albanians are exploring trade options with other Western nations, especially Italy, Greece, France, the Federal Republic of Germany, Yugoslavia, and Spain. Prior to 1974, the United States was importing Albanian ore reexported by Yugoslavia, and more recently has been purchasing Albanian chrome (25,000 tons in 1977) through brokers. Total U.S. imports from Albania were valued at US$2.5 million in 1976 and US$3.4 million in 1977, and are expected to rise in 1978. Albania has bought from the United States videotape equipment and cattle hides. The 1976-77 U.S. trade with Albania is summarized in the following table:

Commodity	Albanian exports to U.S. (million US dollars)		Albanian imports from U.S. (million US dollars)	
	1976	1977	1976	1977
Crude materials, inedible	$2.58	$3.33	$0.42	$0.27
Mineral fuels, lubricants	--	--	--	1.81
Chemicals	.01	.02	--	.03
Manufactured goods	--	--	.08	--
Machinery and transport	--	.04	--	--
Miscellaneous manufactured articles	--	.01	.58	.07
Total	2.54	3.40	1.08	2.18

A trade agreement between Albania and the Democratic Republic of Germany was signed in 1977. Albanian imports are to consist mainly of machinery and equipment for agriculture and shipbuilding, chemical products, and scientific instruments. Albania agreed to export chromite, copper cable, agricultural products, and consumer goods to the Democratic Republic of Germany. Under a similar agreement, Albania will export chrome, iron ore, bitumen, and agricultural products to Poland in exchange for machinery and equipment, metallurgical goods, and chemicals.

COMMODITY REVIEW

METALS

Chromite.—Albania is one of the world's largest chrome ore producers and claims that it is first in the production of chromite per capita and second in the production of metallurgical chromite.[12] In 1977, the country produced 880,000 metric tons of chromite, which is a 6% increase over the 1976 production. The current 5-year plan calls for the production of 1,250,000 tons of chromite by 1980, with 990,000 tons planned for 1978, and 1,110 tons planned for 1979. The trend of the Albanian current 5-year chromite plan is summarized in the following table, in metric tons:

	Actual		Planned		
	1976	1977	1978	1979	1980
Chromite production (tons)	830,000	888,000	990,000	1,110,000	1,250,000
Chromite exports	690,000	720,000	800,000	900,000	1,000
U.S. imports	18,000	25,000	43,000	--	--

The Albanian chrome ore is suitable both for metallurgical and refractory applications. The average Cr_2O_3 content is 43% and the ratio of Cr_2O_3:FeO=3. The guaranteed Cr_2O_3 content is 42% and pricing is usually based on 44% Cr_2O_3 with maximum 10.5% SiO_2. The average grade (Cr_2O_3 content) of Albanian exported chrome ore has been increasing steadily from 22.8% in 1960, to 41% to 46% in 1974, when about 25% of Albanian chrome ore was processed. Mineralimpeks, Albania's state-controlled export agency, markets two grades of chrome ore: (1) a medium-grade, lumpy ore at 42% to 44% Cr_2O_3 content, and (2) a high-grade concentrate at 48% to 50% Cr_2O_3. Chrome ore exported to Yugoslavia is of two grades: (1) A-I and A-II is from 45% to 48% (and over) Cr_2O_3, and (2) A-III is 45% Cr_2O_3 and less. In 1977, Albania exported 27,249 tons of chrome ore to Japan.[13]

The Todo Manco mine at Martenesh is the country's largest chromium producing mine and is able to process 200,000 tons per year of concentrates. A similar beneficiation plant is being installed at Bulgiza and is intended for production of concentrates with over 50% Cr_2O_3. Another concentrator, scheduled to become operational by 1980, is under construction at Kam-Kalimash.

The Albanian chrome deposits occur in the Lower Jurassic beds (harzburgites), the deformed Balkan-Asia Minor ultramafic province, in the Dinaride extension of the Alpine mountain chain. The ore occurs as podiform deposits, similar to those of Turkey, containing tens of thousands to several hundred thousand tons. These lenses are found at shallow depths and are mined partly underground and partly by open cast methods.

Albania's total chrome ore reserves have been estimated at 21.5 million tons. Of this total, 6.5 million tons are measured and indicated reserves and 15 million tons are potential reserves. These reserves are expected to last for another 20 years.

Copper.—Estimated 1977 production of copper ore remained as in 1976, at 600,000 tons. The metal content of mine copper and smelter output were 9,000 tons each. Reportedly, the blister copper production plan was exceeded by 6% in the first 9 months of 1977. The 1978 output is expected to increase for smelter output by approximately 6%. The 1980 copper ore production goal is set to be 55% greater than in 1975.

Almost half of Albania's copper is produced in the Mirditë district, which includes mines, concentrators, and smelters. The mining industry specifically accounts for more than 90% of the district's industrial production. Pyrite is also mined as a byproduct of copper in the Mirditë district.

Albania has three copper smelting plants, the Laç in the Kruja district north of Tirana, will be the largest, once completed in 1979-80. The two other smelting plants are located at Kurbnesh (Mirditë district) and Zall-Rec in the Kukës district. In 1977, a copper concentrator was under construction in Fushe Arrez in the Pukë district, to be operational in 1978.

Digitized by Google

Albanian copper ore reserves are estimated at 50 million tons. Most of the ore is low-grade (sulfide), located in the northern Mirditë district and some in Kruja, Kukës, Pukë, and Shkodër districts. The average recoverable copper content of the ore is 1.9% copper, but the presently mined ore averages 3% copper.

Iron Ore, Nickeliferous.—The 1977 production of nickeliferous iron ore was estimated at 760,000 tons, a 9% increase over that of 1976. Reportedly, the entire production capacity was utilized domestically at the Elbasan Metallurgical Combine. The country's largest industrial project, the 800,000-ton metallurgical complex, is scheduled to be fully operational for the production of nickel, steel, and cobalt in 1978. No new deposits of iron ore were discovered, nor were any iron ore mines opened in 1977. Work, however, continued in 1977 on the ferrochrome plant in Burrel and the iron-nickel mine and beneficiation plant at Guri-i-Kuq. The total reserves of ferronickel ore remain as estimated previously at 20 million tons, containing 51% iron, 1% to 6% nickel, and 0.06% cobalt.

The target production of nickeliferous iron ore planned for 1980 is 2,145,000 tons, all designed for domestic smelting at the Elbasan steelworks.

The nickeliferous iron ore mines in operation in 1977 or in progress of development, included the following: Bushtrice; Burrell (Mat district), including a beneficiation plant to be commissioned in 1979; Cervenaka; Guri-i-Kuq (Pogradec district); Korcë; Librazhjd, Mamez; Pishkash (Lake Ohrid); and Pogradec (Pogradec district). Deposits of nickeliferous ore also are found at Kukës, together with chromite and copper occurrences.

Iron and Steel.—In 1977, the Elbasan Metallurgical Complex was still the largest project in Albania. The equipment and construction supervision were continued to be supplied by China. The complex is designed to produce pig iron, high-strength steels, and various rolled and laminated products. The complex produced stainless steel for the first time in 1977. Reportedly, 23 types of steel have now been produced.[14] During the last 9 months of 1977, the Elbasan complex produced 6.5% of rolled steel above plan. Equipment and machinery parts are also manufactured, as are many other products. The third electric smelting furnace is to be added to the combine in 1978, and a new concentrator will supply the complex with nickeliferous iron ore from the mines at Guri-i-Kuq and Prrenjas.

NONMETALS

Cement.—The 1977 estimated production of cement was 750,000 tons, while the estimated annual kiln capacity was at 800,000 tons. The 1978 production is set at 900,000 with a corresponding increase in kiln capacity. In 1977, Albania imported 20,000 tons of cement and exported 80,000 tons, the total approximate consumption was 690,000 tons.[15] Production in 1980 is to increase 55% compared with 1975.

Albania has five cement plants, all belonging to the State Cement Co. located at Elbasan, Fusë-Krujë, Shkodër, Tirana, and Vlora. The plants extend along Albania's west coast from north to south.

Fertilizer Materials.—Estimated production of nitrogenous fertilizers in 1977 was 260,000 tons (36,000 tons nitrogen content), and the estimated production of phosphatic fertilizer was 65,000 tons (21,000 tons P_2O_5 content). Planned production for the nitrogenous fertilizers is set at 400,000 tons for 1980. The production of nitrogenous fertilizer has increased steadily since 1970 when it was 6,000 tons. The output of phosphatic fertilizers, on the other hand, has remained relatively stable. Most of Albania's raw materials for fertilizer production are imported. Phosphatic fertilizers are produced from phosphate imported from North Africa and potash is imported from Italy (approximately 2,000 tons per year, K_2O content) for the manufacture of potassic compounds. In 1977, Albania imported a total of 81,000 tons of phosphate rock, mostly from Egypt and Syria (66,000 tons), some from Morocco (7,000 tons), and Algeria (8,000 tons).[16]

The Albanian chemical industry has been developing since 1960, and now supplies all of its domestic needs for nitrogenous and phosphatic fertilizers including sulfuric acid (1977 consumption of sulfur was 2,000 tons) and caustic and calcined soda. According to the 5-year plan, investments in the chemical industry will be 51% higher than in the 1971-75 period and will constitute more than 53% of all industrial investments. Albania has two plants for the production of nitrogenous and phosphatic fertilizers and a limited quantity of phosphate rock deposits. One nitrogenous fertilizer plant is located at Fieri (Fieri district). The construction since 1975 of a urea plant at Fieri is expected to double Albania's production of nitrogenous fertilizer. The plant was expected to become operational in 1976 or

Digitized by Google

1977. An ammonia plant is also located at Fieri, with an estimated annual capacity of 50,000 tons. Another ammonium nitrate plant was supposedly constructed at Laç.

Production of phosphatic fertilizers is centered at Laç (Kruje district), manufacturing granulated and powdered superphosphate. Albania plans to process its nonphosphatic ore at Laç for the production of phosphoric acid and triple superphosphate. Reportedly, several sedimentary phosphate rock deposits, containing 7% to 18% P_2O_5, occur in the Cretaceous Formations near Nivice and Fushe-Bardhe, Sarandi district in southern Albania.

MINERAL FUELS

Albania is self-sufficient in energy and even exports oil, electrical energy, and perhaps some coal. As in other centrally planned economy countries, measures were underway in 1977 for the conservation of energy and the promotion of coal utilization in lieu of oil and gas. The year 1977 was an especially dry year and strict energy conservation measures were in force for the utilization of hydroelectric power. This especially effected major factories, such as the Elbasan Metallurgical Complex, the polyvinyl chloride factory in Vlora, and the nitrogen and urea plant in Fieri, which together consume over 25% of the total electrical energy requirements. Plans for 1978, however, call for the generation of 34% more total electric energy. In addition to the 15 or so hydroelectric powerplants, there are also at least 10 thermoelectric powerplants fueled by oil, gas, and coal, located at Cerrik, Fieri, Fierzë, Korcë, Laç, Maliq, Salite e Malit, Stalin City, Tirana, and Vlora.[17]

The production of primary energy in Albania in 1977 was slightly higher than in the previous year, reaching 4.18 million tons standard coal equivalent (SCE). Exports and imports of primary energy remained unchanged from 1976, at 1.36 million and 20,000 tons SCE respectively. Albania's consumption of primary energy in 1977 showed only a slight (1%) increase. Petroleum accounted for 52% of the total Albanian energy consumption in 1977, coal and lignite supplied 25%, natural gas 17%, and hydroelectricity 6%. Total primary energy balances for Albania in 1976-77 are shown in table 4.

Table 4.—Albania: Total primary energy balance for 1976 and 1977

(Million tons of standard coal equivalent[1])

Year	Total primary energy	Coal (lignite, anthracite, bituminous) coke	Crude oil and petroleum products	Natural and associated gas	Hydropower
1976:[2]					
Production	4.14	0.68	2.79	0.47	0.20
Imports	.02	.02	--	--	--
Exports	1.36	--	1.31	--	.05

[1]1 ton of standard coal equivalent (SCE)=7,000,000 kilocalories. Conversion factors used are lignite, 0.7; crude oil, 1.47; natural gas, 1.33 (per 1,000 cubic meters); hydroelectric power, 0.125 (per 1,000 kilowatt-hours).
[2]Data obtained from various Albanian sources and estimates.

Source: United Nations. World Energy Supplies. Statistical Papers, Series J, No. 18, 1975.

Coal.—Lignite is the major type of coal mined in Albania and the 1977 estimated production was 1,000,000 tons. Some subbituminous coal is mined but Albania has no high-quality anthracite or bituminous coal. A small quantity of lignite and coke is also exported, mostly to Yugoslavia. The 1980 planned production is 1,800,000 tons and at that time about 60% of the domestic lignite will be beneficiated. Much of Albania's metallurgical coal is, however, imported. The Elbasan Metallurgical Complex, for example, utilizes up to 15% of noncoking coal from the Memaliaj deposit, while the remaining 85% is imported. Reportedly, new coke oven facilities were put into operation in 1977 at the coking plant of the Elbasan complex. They are designed to produce coke byproducts such as tar, sulfur, and ammonium sulfate. Most of Albania's

Digitized by Google

coal does not coke directly, thus necessitating import of metallurgical coal. Most of the coal has also a high ash and sulfur content, except perhaps that from the Alarupi and Bezhani mines in the southeast.[18]

Albanian coalfields may be grouped into four general geographical areas, three of them generally extending in a southeast-northwest line from Korcë to Durres, with a fourth located in the south at Memaliaj. Two of the fields, however, lie outside of this trend, one in the east in the Pogradec district (Alarupi and Cervenake mines), and the other in the Lushnjë district in the west, southwest of the Elbasan district.

Natural Gas.—Estimated production of natural gas in 1977 remained unchanged from 1976, at 12,370 million cubic feet. Although Albania is self-sufficient in gas, it planned to increase the gas output in the current 5-year plan to 15,715 million cubic feet in 1980. Total Albanian gas reserves are estimated at about 8 trillion cubic feet. About 35% of the nations total area (mostly southeast) is considered promising for oil and gas. Recent gas discoveries, for example, were reported in the Lushnjë district, at Diviakë and Budulinë. Gas also occurs at Marineze, in the Fieri district, just south of the Lushnjë district. Domestically natural gas is used in the petrochemical industry, fertilizer plants, in thermal power generation, and by the domestic sector.

Petroleum.—Albania's 1977 crude oil production stabilized at about the 1976 level, when it turned sharply downward from 1975. Albania continued to import petroleum products but also exported some in addition to the crude oil. Albania's last 5-year plan called for the production of 19 million barrels per year by 1975 and hoped to increase crude production by 11% during the current 5-year plan ending in 1980, primarily for export purposes.

Reportedly, in spite of the Albanian-Chinese rift, the construction of the oil refinery at Ballësh near Vlorë (Vlorë district) continued on schedule. By the end of the current 5-year plan period, the Albanian oilfields and refineries should be connected by an oil pipeline system, terminating at the Vlorë seaport. The new refinery at Ballësh, the second largest investment project in Albania after the Elbasan Metallurgical Complex, is rated at 1 million tons annual (20,000 barrels per day) capacity. In general, Albania's refinery capacity (2 million tons annually), appears more than adequate to meet domestic needs. Older installations are located near the Stalin oilfield (0.5 million tons), the City of Cerrik (0.5 million tons), and at Fieri (1.0 million tons).

Albanian oilfields ore concentrated in the southwestern part of the country, in three areas: The Stalin, the Marineze, and the Patos fields. A bitumen occurrence is also located just south of Patos, in the Selenice area. Reportedly, a total of eight oil- and gasfields are known to exist in Albania. The offshore Adriatic shelf is also regarded as having good hydrocarbon prospects, as is the Vlore district. The Marineze field, discovered in 1957 by Russians, is believed to be the largest Albanian oil- and gasfield. It produces light oil from six stratigraphic zones to a depth of 1,400 meters. Reportedly, none of Albania's known oil and gas deposits is deeper than 1,700 meters. The Stalin oilfield (previously known as Kucebo), found by Italians in 1936 and Albania's oldest producing field, and the Patos field, onstream since 1939, are nearing depletion. Both fields provide heavy oil.[19]

The Mineral Industry of Algeria

By David E. Morse[1]

Algeria remained one of Africa's major producers of petroleum and natural gas, cement, mercury, and barite. Production of copper, lead and zinc concentrates, phosphate rock, iron ore, and clay minerals was modest by world standards. The State-owned Société Nationale de Recherches et d' Exploitations Minières (SONAREM) carried out the marketing, exploration, production and processing of mineral commodities. Oil and natural gas activities were dominated by the State-owned Société Nationale pour la Recherche, la Production, le Transport, la Transformation et la Commercialisation des Hydocarbures (SONATRACH). SONAREM conducted investigations in northern Algeria particularly on nonmetallic industrial minerals and increased efforts to evaluate metallic ore deposits of copper, lead, mercury, and zinc. SONAREM also conducted field exploration in the remote Hoggar Mountains of southern Algeria. Although SONATRACH continued petroleum exploration and development, its major effort was geared toward developing Algeria's prodigious natural gas reserves.

The Algerian economy continued its strong growth in 1977, with the real gross domestic product (GDP) increasing 8.8%. The hydrocarbon sector retained its position as the largest contributor to the GDP but grew at a rate of 7% less than the economy as a whole. The mining sector's contribution to the GDP remained slight and did not grow during the year.

During 1977, Algeria's state corporations budgeted $1.2 billion[2] for investments in the petroleum and natural gas industries, $500 million for the steel industry, $380 million in the construction materials industry, and $340 million in chemical industries.

In 1977, Société Nationale Algerienne de l'Electricité et du Gaz (SONELGAZ) and Impiante e Nucleari AMN of Genoa, Italy, signed a contract for the construction of a gas-fired powerplant on the Mediterranean coast east of Arzew. The plant was to have three 168-megawatt generators and be in full operation in 1982. During 1977, construction was underway on five electric powerplants that would bring Algeria's generation capacity to 1,840 megawatts. SONEGAZ also planned to build a 600-megawatt powerplant near M'Sala to furnish power for Algeria's first aluminum smelter.

PRODUCTION

Mineral production in Algeria exhibited many minor changes in 1977, but the overall results were similar to those of the preceding few years. Output of crude oil, natural gas, iron ore, phosphate rock, and cement increased substantially compared with that of 1976. Barite, lead, and zinc declined significantly during the year. Mining and quarrying represented less than 0.5% of the GDP in 1977, whereas the hydrocarbon sector's contribution was about 28%. Approximately 60% of Algeria's nonhydrocarbon mineral production was consumed domestically. Domestic demand consumed nearly 8% of crude oil production and 10% of natural gas output.

[e]Estimate. [p]Preliminary. [r]Revised. NA Not available.

[1]In addition to the commodities listed, secondary aluminum, secondary lead, and secondary copper may be produced in small quantities, and additional crude construction materials (crude clays and stone) presumably are produced for local consumption, but output is unreported and available information is inadequate to make reliable estimates of output levels.

[2]Includes plasters as follows, in tons: 1975—49,441; 1976—e50,000; 1977—e50,000.

[3]Includes lease condensate.

TRADE

Algeria exported large quantities of crude oil, liquefied natural gas (LNG), phosphate rock, and mercury to Europe and the United States during 1977. Minor quantities of iron ore, and concentrates of copper, lead, and zinc were exported to Europe. The

Digitized by Google

United States imported about 197 million barrels of Algerian crude oil in 1977, an increase of 47 million barrels compared with the 1976 level, which represented 8.2% of U.S. crude imports. The value of exported crude oil and refined petroleum products was approximately $5.7 billion and represented 91% of the value of Algeria's total exports. LNG exports in 1977 were 6.8 billion cubic meters, and exports of nonhydrocarbon mineral products from domestic mines were valued at approximately $45 million.

COMMODITY REVIEW

METALS

Aluminum.—Algeria planned to bring its first aluminum smelter online in 1982. The 125,000-ton-per-year plant was to be built with assistance from the Soviet Union at M'sala in the Sétif district of north-central Algeria. Raw materials for the project, mainly alumina, would be imported from Jamaica and Guinea. Negotiations were underway with the U.S.S.R. for the construction of a second 125,000-ton-per-year aluminum smelter, but no agreement had been finalized by yearend.

Digitized by Google

Iron Ore.—Expansion of the Quenza-Bou Khadra iron ore mining operation was completed in 1977, raising capacity to 5 million tons per year. Production increased by 400,000 tons to 3.2 million tons in 1977, which reversed the downward trend of the previous 2 years.

Late in 1977, Canadian Pacific Consulting Service Ltd. was commissioned to perform an engineering study for a planned 1,500-kilometer mining railway system to be built in western Algeria. The railway would link the 1,000-million-ton iron ore deposit at Gara Djebilet to a new export harbor on the Western Mediterranean at the mouth of the la Macta River near Oran. The study was to commence in early 1978 and require 2 1/2 years for completion.

Iron and Steel.—The expansion of the El Hadjar steel plant continued in 1977. The expansion was to be completed in 1979 and raise Algeria's raw steel capacity to 2 million tons per year.

In April, Société Nationale de Siderurgie (SNS) signed a contract with a Belgian engineering firm to supervise the construction of a 1.2-million-ton-per-year steel mill to be built 12 kilometers east of Djidjelli on the Mediterranean coast. The project was to use domestic natural gas as a reductant and require the construction of port facilities, a new thermal power station, rail and road connections, and a village to house the steel mill employees.

Mercury.—During 1977, Algerian mercury production of 30,000 76-pound flasks accounted for nearly one-eighth of primary world mercury production. Algeria maintained a high production level despite low prices on the world market and a domestic demand of only 200 flasks per year.

Other Metals.—SONAREM continued investigations to assess the mineral potential of the Ahaggar massif south of the Hoggar Mountains in the remote desert region of southern Algeria where deposits of gold, tin, tungsten, and uranium have been located. Hydrogeologic investigations reportedly found sufficient quantities of water to support the development of uranium deposits at Timgaouine and Abankor. SONAREM planned to initiate the production of approximately 700 tons per year of U_3O_8 in the early 1980's from Ahagger vein deposits.

NONMETALS

Barite.—SONAREM planned to increase barite production capacity to 150,000 tons per year by expanding the Mizab and Affensou mines, and to complete construction of a 50,000-ton-per-year grinding plant at Mekla. During 1977, barite production decreased 33% compared with the 1976 level and was below domestic demand of about 80,000 tons.

Cement.—Algerian cement capacity increased to 4.5 million tons per year when the 1-million-ton-per-year plants at Zahana near Oran and at Al Asnam near Algiers were commissioned. Cement production has not met domestic demand for years and, in an effort to reduce cement imports, Société Nationale des Matériaux de Construction (SNMC) was in the midst of an expansion program to bring Algerian cement capacity to over 10 million tons per year by 1980. Cement plants under construction in 1977 included four plants scheduled for completion in 1978 at Ain el Kebira near Sétif, Beni Saf near Oran, Hamma-Bouziane near Constantine, and Saida near Mascara; a second 1-million-ton-per-year plant at Al Asnam to be brought on-line in 1979; and three plants to be completed in 1980 at Bouira, Batna, and Djelfa.

Phosphate Rock.—Based on an estimated reserve of 200 million tons of phosphate rock grading, 55% bone phosphate of lime at Djebel Onk, Algeria planned to increase production capacity to 6 million tons per year by 1980. Phosphate production increased to over 1 million tons, and exports rose 26% over those of 1976 to 698,000 tons, with 656,000 tons going to the European market. A new 90,000-ton-per-year dedusting plant was commissioned at Djebel Onk late in the year. SONAREM planned to build a new fertilizer complex at Tebessa that was to produce 528,000 tons per year of sulfuric acid, 165,000 tons per year of P_2O_5 phosphoric acid, and 285,000 tons per year of triple superphosphate.

In September SONAREM signed a new 3-year agreement to continue phosphate rock shipments to Hungary, although the details of the agreement were not announced. Algeria exported 89,000 tons of phosphate rock to Hungary in 1976 and 130,000 tons in 1977. In August, SONAREM agreed to supply Finland's Kemira Oy with 60,000 tons per year of phosphate rock in return for viscose fiber (rayon) of equal value. The period covered by the agreement was from 1977 through 1979 with provisions for possible extension. In May, SONAREM contracted to ship phosphate rock to Brazil, and Brazil agreed to begin shipments of

Digitized by Google

automobiles to Algeria commencing in October. By yearend, Algeria had shipped approximately 87,000 tons of phosphate rock to Brazil.

MINERAL FUELS

Natural Gas.—Marketed Algerian natural gas production was approximately 8.7 billion cubic meters in 1977. By yearend, based on a reserve of 3,550 billion cubic meters of natural gas, Algeria had negotiated contracts for the export of approximately 76 billion cubic meters of natural gas per year with most deliveries to begin the 1980-84 period. Firm contracts included 44 billion cubic meters to be shipped as liquefied natural gas (LNG) and 12 billion as pipeline gas. Two LNG contracts for 10 billion cubic meters per year each, which had been negotiated with U.S. companies, had not received U.S. Department of Energy approval by yearend 1977.

To meet its commitments, Algeria embarked on a huge expansion program to develop the full spectrum of facilities required to produce 110 billion cubic meters per year of pipeline gas and 22 million tons per year of natural gas liquids (NGL). Additional pipelines were to be built to connect the prolific Hassi R'Mel field to Skikda and Arzew where LNG facilities were in operation and under construction.

Table 4.—Algeria: LNG plants in operation, under construction, and planned (1977)

Plant	Location	Capacity (billion cubic meters per year)	Startup date
Camel	Arzew	1.5	1964
Skikda 1:			
Trains 1, 2 and 3	Skikda	4.2	1972-1973

NA Not available.

SONATRACH signed a contract in May with Japan Gasoline Co. Ltd., and C. Itoh & Co. for the construction of a fifth natural gas processing facility at Hassi R'Mel that would produce 21 billion cubic meters per year of dry gas and 4.5 million tons per year of NGL. Italy's Ente Nazionale Idrocarburi (ENI) and SONATRACH signed an agreement in October for the delivery of 12 billion cubic meters per year of natural gas to Italy. Natural gas, which was to be shipped by pipeline, will originate at Hassi R'Mel, pass through Tunisia to Cape Bon, cross the Mediterranean under the Straight of Sicily, traverse Sicily, and cross the Strait of Messina to the Italian mainland. Projected cost of the pipeline was $3.0 billion, with deliveries commencing in 1981.

The Government of Algeria planned to have all the components of the natural gas expansion scheme online by 1985. When in full production, natural gas and NGL are expected to provide Algeria with approximately $6 billion per year in foreign exchange earnings.

Petroleum.—During 1977, petroleum production increased 6.5% compared with that of 1976, and output of 53.5 million tons was the highest production level attained in Algeria. Approximately 90% of production was exported as crude; the remainder was processed by domestic refiners. Exports of petroleum products were estimated at 1.4 million tons during the year.

Drilling activity in Algeria was sustained at a fairly high level and resulted in 11 oil wells and 30 gas wells during the year. Of the total footage drilled during 1977, less than 25% was for exploratory drilling; and of 11 wildcats spudded by companies working with SONATRACH, 1 found oil, 1 gas, and 9 were dry. Total Algerie drilled the country's first offshore well, the Hobibas 1, a dry hole, approximately 115 kilometers off Oran in water 1 kilometer deep.

Algeria's petroleum refineries at Arzew, Algiers, and Hassi Messaoud had a combined capacity of 5.7 million tons per year in 1977, and output was approximately 4.95 million tons during the year. Algeria plan-

Digitized by Google

ned to increase domestic refining capacity to about 30 million tons per year with new oil refineries at Skikda (15 million tons per year), Hassi Messaoud (1 million tons per year), In Amenas (500,000 tons per year), and Bejaĭa (7.5 million tons per year). The Skikda, Hassi Messaoud, and In Amenas plants were scheduled to come onstream in 1979-80. The Bejaïa refinery was in the planning stage.

The Mineral Industry of Angola

By Janice L. W. Jolly[1]

Crude petroleum production continued to be the mainstay of the Angolan economy, which was still laboring at the low levels brought about by the civil war. Both petroleum and diamond production increased over those of 1976. Estimated variously at $600 million to $800 million,[2] petroleum revenues provided most of the Government's operating revenue and were the major component of the 1977 gross domestic product (GDP) estimated to be 50% to 80% below the 1974 level of $3 billion. A long list of nationalizations and seizures of abandoned businesses was announced as the Government began measures toward reconstruction. A new currency, the kwanza, was announced in January. The kwanza, divided into 100 lwei, replaced the Angolan escudo and is not convertible on the international market.[3]

With Angola's industrial production running at about 40% of pre-civil war levels and with a serious shortage of skilled workers preventing utilization of production capacities, the ruling Movimento Popular para a Libertação de Angola (MPLA) Congress was considering the steps necessary for economic recovery. These included giving the mining, petroleum, and industrial sectors high development priority.[4]

Measures to be adopted as a basis for reconstruction included the following: The State industry sector was to be enlarged and consolidated by nationalization. Government enterprise activities were to be improved and were to set standards for the expected creation and operation of new mixed private-Government enterprises. Government guidelines were to be established for private enterprises so that their operation would coincide with more general interests of the national economy. Industrial production and distribution were to be subject to Government control and planning. Literacy and technical training were to be developed for all branches of industry. New ministries or directorates were to be formed to carry out specific tasks.

National Directorates for Electrical Energy, for the Petroleum Industry, and for Geology and Mining Industry were established by Decree No. 66/77 on August 14. The National Directorate for Geology and Mining Industry, under the Ministry of Industry and Power, was to assume a special significance in laying the foundations for a mineral policy and creating the conditions for rational development of the mineral industry. This was to include formation of a new national geological map, concentrating efforts on areas of greatest interest.

Efforts were to be made to revive mining operations by reequipping them and taking the necessary reorganization and technical assistance measures. A new mining law was to be drafted and published. The petroleum industry was to gradually increase output, and the national fuel company, Soc. Nacional de Combustiveis de Angola (SONANGOL), was to be strengthened to insure the Government's leading role in the development of the petroleum industry. Exports of refined petroleum products were to be increased, as were other mineral exports.

An all-out effort to improve basic infrastructure such as electricity, roads, and ports was also planned. It was considered particularly important to build the port at Cabinda. Studies were also to be undertaken for the expansion of ports at Luanda, Lobito, and Moçâmedes, which would consider the need for a container facility, construction of new warehouses, and better connections with roads and railroads. The

Digitized by Google

shortage of technicians affected practically every sector. Angola's largest power company, providing 60% of the nation's electricity, was operating with half the skilled personnel considered adequate.

Tanganyika Concession's Benguela Railway in Angola continued to operate within the country under great difficulties, but had carried no international traffic since August 1975. No income was received from the Railway, whose future depended upon resumption of international traffic. The line was open between Lobito and Bié and from the Zaire border to Luena, but the central portion was far from secure. A decree was issued in May 1977 canceling the concession for operation of the Amboim railroad and port, which had been operated by Amboim Railway Co., Ltd., since 1923. All assets of the company were to be controlled by the Angolan Ports, Railways and Transportation Service without any indemnification. The railroad is 150 kilometers long and links the port to the city of Gabela.

The Foreign Relations Ministry published Declaration No. 159/75 that set the extent of territorial waters at 20 miles, measured from the shoreline. In high seas areas contiguous to its territorial waters, extending a distance of 200 miles from the shoreline, the State of Angola claimed the right, conferred upon it by international law, to exercise the control required to prevent violations and to guarantee the country's legitimate defense. Fishing rights also extend to the 200-mile limit.[5]

The Angolan Government continued its refusal to open the water reservoir into the Cunene River on the Angolan-South-West African frontier. As a consequence, the hydroelectric dam at Ruacaná, although complete, was not in operation. The dam, designed in 1969 in collaboration with Portuguese colonial authorities and built by the Republic of South Africa, was finished in 1977 but was unable to operate because of the Angolan veto. Cost of the Ruacaná project was estimated at over $200 million and was being borne by the South African Government. The electric power was intended for South-West African and southern Angolan areas.

PRODUCTION AND TRADE

In 1977, 62.4 million barrels of crude petroleum was produced, including about 44 million barrels from Gulf Oil Corp.'s Cabinda wells and 19 million barrels from Angola proper. Large production increases were credited to the N'Zombo (1973) and Quinfuquena (1975) wells, which were producing an average of 39,194 barrels and 6,799 barrels per day, respectively.[6]

Angola was to begin selling oil to Zambia, and there was discussion of building an oil pipeline between the two countries. In August, there were reports that a road link was being planned to connect the Zambian Copperbelt to the Benguela Railway, bypassing Zaire.

Total Angolan diamond production was estimated at about 353,000 carats. A 15% increase in Central Selling Organization (CSO) prices announced in March contributed to improved revenues from this sector of the mineral industry.

COMMODITY REVIEW

METALS

Iron Ore.—Two contracts were awarded to the Yugoslav company Energoprojekt to reopen the Cassinga iron ore mine, which has been closed since August 1975. Transport of ore in stock was part of the agreement. Angola's iron ore export terminal can accommodate 200,000-deadweight-ton ships and has a 1.2-million-ton stockpile capacity. The Krupp shiploader and terminal have a load rate of 3,500 tons per hour. Iron ore reserves at Cassinga were estimated at 100 million tons of eluvial hematite ore with 62% to 64% iron and 2 billion tons of itabirite ore with 40% to 50% iron. Taconite ore, estimated at 92 million tons with an average of 32% iron, occurs at Cassala-Quitungo.

NONMETALS

Cement.—Angola's two cement companies were included in the first series of industry confiscations in accordance with Decree No. 72/77. One was owned by Cia. de Cimento Secil du Ultramar S.A.R.L. in Luanda, and the other was owned by Cia. des Cimentos de Angola S.A.R.L. in Lobito. The Luanda plant was a fuel-oil-fired plant with a 750,000-ton-per-year capacity, and the Lobito plant had a 150,000-ton-per-year capacity. Industrial Construction Co. and other cement and ceramic products companies headquartered in Luanda were also confiscated. The State-owned National Cement Enterprise was to be established with headquarters in Lobito under the jurisdiction of the Ministry of Construction and Housing.[7]

Diamond.—On August 30, a decree was published expanding the Angolan Government's 11% holding (200,000 shares) in Cia. de Diamantes de Angola (DIAMANG) to 60.85% (1,052,755 shares). The amount and manner of indemnity for the nationalized Portuguese shares were to be determined by the Angolan Council of Ministers. The right to indemnity may be denied to former holders of nationalized shares found guilty

Digitized by Google

of fraud. Shares not subject to the nationalization were owned by the following companies: Soc. Générale de Belgique S.A., Soc. d'Entreprise et d'Investissements de Beceka S.A. (SIBEKA), Diamond Corp. (Pty.) Ltd. (a subsidiary of the De Beers group), John S. G. Memorial Foundation, S. R. and D. F. Guggenheim Foundations, Pacific Tin Consolidated Corp., Morgan Guaranty and Trust Co., G. E. Bank Co., Pinto Magalhaes Bank, Portuguese Intercontinental Bank, Totta and Acores Bank, National Overseas Bank, Portuguese Atlantic Bank, Fonsecas and Burnay Bank, Caixa General Deposit and Social Security Fund, Lisbon Water Co., Tagus Insurance Co., Labor Insurance Co., Swiss Banks Co., and Swiss Bank Corp. At a special meeting on November 29, DIAMANG's new directors were elected; of the eight directors, four were Angolans, including the chairman of the board. Two directors were to represent the Belgian stockholders group, and the British and United States groups each had one representative. Approximately 18,000 persons were reported as employed in diamond mining in the Lunda District.

DIAMANG's 1977 diamond production was reported at 352,700 carats, up about 4% over the lowest level of 1976. As a result of higher diamond prices during the year, revenues rose more sharply. Plans were being made to increase production, including recruitment of more expatriate workers. A management contract was under negotiation with De Beers.

The Diamond Security Department (DSD) was established under the Directorate of Intelligence and Security of Angola (DISA). With its headquarters in Dundo and sections located at Andrada, Cuando, and Luanda, the DSD was to coordinate its activities with DIAMANG and civil police corps in maintaining surveillance of all operations involving prospecting, mining, classification, evaluation, transportation, and marketing of diamond, with special care for its security and prevention of illegal traffic in diamond.[8]

Fertilizer Materials.—*Phosphate Rock.*—Phosphate exploration and the fertilizer plant project may be revived. A meeting was held with Bulgarian representatives to discuss possible Bulgarian technical cooperation in an exploration program. In 1975, it had been reported that Ammonição Portuguese had plans for a $40 million fertilizer complex using phosphate rock at Caala.

Salt.—The Ministry of Internal Trade issued new regulations for the sale of salt in the country to provide more equitable distribution. All salt-producing companies were obligated to sell their entire salt production to the National Food Products Distributing Co. These firms were to receive production quotas in accordance with guidelines issued by the State Wholesale Firm for Internal Trade in the province in which the production unit was located. Measures were taken to improve wages for workers at the Capulo saltworks in Ambriz.

MINERAL FUELS

Petroleum and Natural Gas.—The national petroleum company SONANGOL was negotiating a new contract with Gulf for production, prospecting, and development of petroleum in Cabinda. SONANGOL, the only firm with mineral rights for exploration and production of liquid and gaseous hydrocarbons, was expected to acquire at least 51% of Cabinda Gulf Oil Co. Talks were being held with Texaco Inc. and the Belgian firm Petrofina S.A. on possible oil prospecting off the northern Angolan shore. The former Portuguese- and Belgian-operated (Petrofina) companies Soc. Portuguesa Exploração de Petroleos Angol S.A.R.L. and Cia. de Petróleos de Angola (PETRANGOL) were already nationalized by the MPLA Government. Petrofina held 59% of the shares in the Luanda refinery.

Petroleum was being produced mainly from the Cabinda enclave, where Gulf had numerous offshore wells. Cabinda's production began from the Malongo North and Malongo South Fields in 1968 and reached a peak of 167,000 barrels per day in 1974. Gulf's production fell sharply after the civil war to 78,000 barrels per day during 1976, but increased again to an average of 122,700 barrels per day in 1977. Gulf's production constituted about 71% of Angola's total crude petroleum output. The PETRANGOL fields (Texaco, Angol, and Petrangol) of northern Angola accounted for the remainder.

Cabinda Gulf Oil planned to initiate new projects costing $38 million. About half of this sum was to be furnished by the Angolan Government under new contractual arrangements. The investments were to include a gas injection scheme to improve recovery from existing wells and exploration for new offshore wells. Angola received tax and royalty payments from Gulf estimated at $460 million in 1977, which provided an estimated 60% to 80% of the Angolan

Digitized by Google

Government's operating revenue.

Angola's proved crude oil reserves were estimated at 1.2 billion barrels in January and natural gas reserves at about 1.1 trillion cubic feet. Natural gas was being produced at an average rate of 7 billion cubic feet per month.

PETRANGOL awarded the Italian company SNAM Progetti S.p.A. a contract for construction of a new marine terminal at Quinfuquena on Angola's northern coast. To include onshore and offshore pipelines, a tank farm, and pumping station, the terminal was expected to be completed by early 1980.[9] PETRANGOL's Luanda petroleum refinery was producing about 14,000 barrels per day of refined products; it had a processing capacity of about 32,000 barrels per day.

Decree No. 85/76 extended the prospecting period for the PETRANGOL concession zone to December 31, 1977, which made it possible to reexamine projects and continue prospecting in the Soyo region on the N'Zombo and Quinfuquena structures. Onshore in the Cuanza Basin, reinterpretation and study of geological and seismic data previously recorded were undertaken. The final demarcation of the Legua deposit was completed. Talks were started with the Government on dividing the activities of the company into separate enterprises, with one devoted to petroleum prospecting and production and the other to refining.

The Mineral Industry of Argentina

By Orlando Martino[1]

The Argentine economy recovered in 1977 following the production declines of the 2 prior years. With a real growth of 4.7%, the gross domestic product (GDP) was estimated at $48.5 billion[2] at current prices. Although the rate of inflation was reduced by one-half, it continued high at 170%, among the highest in the world.

Although Argentina has substantial mineral potential, the value of nonfuel mineral output in 1977 represented less than 1% of the GDP. The value of petroleum and natural gas output, however, was 1.2% of the GDP and increased 8% over that of 1976. The major part of the country's limited mineral production was oriented to meeting the needs of the industrial sector. Imports of alumina, copper, iron ore, manganese ore, and metallurgical coal were required to satisfy growing domestic demand.

As the third largest producer of crude petroleum and one of the leading producers of natural gas in Latin America, Argentina was less dependent upon foreign energy sources. State-owned Yacimientos Petrolíferos Fiscales (YPF) and Gas del Estado were actively engaged in investment programs to enable Argentina to gain self-sufficiency in these mineral fuels by 1985. Argentina had the leading position in Latin America in the application of nuclear reactor technology and during the year became an exporter of this technology to the region for the first time. During 1977, new plant capacity was added for producing uranium concentrate to support the country's nuclear energy program.

The copper-molybdenum discovery at Famatina in La Rioja Province on the eastern side of the Andean Range was an important result of the activities of the Servicio Minero and Derección General de Fabricaciones Militares (DGFM), the Army's industrial complex with large mining interests in Argentina. Further exploration was underway to determine its potential for domestic and foreign investment.

Government Policies and Programs.—The Military Junta continued its economic stabilization program to reduce the country's strong inflation. Nonetheless a substantial increase in gross fixed investment during 1977 increased the demand for minerals, metals, and other raw materials. Following promulgation of the liberal Foreign Investment Law of August 1976, the increase in direct foreign investment reflected renewed confidence in the investment climate of Argentina. The Government publicly welcomed foreign investment and issued new laws providing for more favorable treatment. Efforts were also made to reduce the Government's role in the economy.

The proposed new Argentine mining legislation remained stalled in the executive branch, and there was no indication of when it would be submitted to the Legislative Advisory Council. The proposed law was considered important to certain pending foreign mineral investments such as the large El Pachón copper project. In July, the Government issued Industrial Promotion Law No. 21608 to strengthen the participation of private enterprise and, among other objectives, to further the installation of new industries in frontier areas and facilitate the transfer of industries away from densely populated cities. Special promotional benefits would be granted to industries that developed regional raw materials processing plants such as smelters and ore concentrators.

The Government also promulgated new

Digitized by Google

transfer of technology through Law No. 20794 in August 1977 which replaced earlier restrictive legislation that greatly impeded the flow of technology to Argentina.

The Government approved a new law to regulate risk association contracts for oil exploration in onshore and offshore areas, and in October, a call for bids was initiated in the Tierra del Fuego zone. As a first step in determining investment priorities in the energy sector, the Secretariat of Energy prepared a global energy balance for the period 1977-85. The Government announced a vast $24 billion plan of investments during a 10-year period providing for the drilling of 7,000 wells with the objective of increasing oil production from 424,000 barrels to 640,000 barrels per day. The energy plan would also expand and strengthen the coal industry and provide for construction of new hydroelectric and nuclear power stations. Of the total, $11.3 billion would be invested directly in the petroleum industry.

The Servicio Geológico Nacional was carrying out an exploration program in the Patagonia region, south of Bariloche in the Andean Cordillera, Santa Cruz Province, where the primary targets are copper and lead.

Argentina took steps to begin exploiting its untapped mineral reserves in the north by opening to development a 550-square-kilometer zone in Catamarca Province that was part of the Federal reserve. This zone was reported to have reserves of copper, manganese, gold, and silver. More than 90% of Argentina remained to be systematically explored.

PRODUCTION

Provisional Government data indicate that nonfuel mineral output on a gross tonnage basis increased 5% in 1977. The greatest growth took place in nonmetallic ores (7%), while output of metallic ores increased 3%. Among nonmetals, notable increases occurred in output of boron minerals (borates) (19%), diatomite (13%), feldspar (13%), fluorspar (11%), and mica (10%); graphite decreased 20%. Production of copper ores increased 7% but continued far short of domestic requirements. Output of iron ore, tin ore, and lithium minerals increased 5%, 6%, and 8%, respectively. Manganese ore output increased only slightly in 1977 but was 70% above the 1975 output. Notable declines were in tungsten ore (11%) and beryllium (8%).

Among mineral fuels, production of coal continued to fall short of targeted increases. The rebound in output of crude petroleum strenthened but remained below the peak of 1972. Natural gas output was up 14%, continuing the upward trend of the decade. Production of uranium concentrate (yellow cake) increased subtantially as new concentration capacity came onstream at Don Otto and Puesto de Los Adobes in Salta and Chubut Provinces.

Table 1.—Argentina: Production of mineral commodities

(Metric tons unless otherwise specified)

Commodity[1]	1975	1976	1977[p]
METALS			
Antimony, mine output, metal content—kilograms	900	2,200	2,200
Beryllium, beryl concentrate, gross weight	167	112	103

[e]Estimate. [p]Preliminary. [r]Revised. NA Not available.

[1]In addition to the commodities listed, cadmium, lime, perlite, and urea are also produced, but output is not reported quantitatively, and available information is inadequate to make reliable estimates of output levels. Titanium-bearing iron sands are also produced with annual production of approximately 100 tons of contained metal, but recovery of titanium oxides is not attempted and the material is used for nonmetallurgical uses.

[2]Hot-rolled semimanufactures only; excludes castings and cold-rolled semimanufactures produced from imported hot-rolled semimanufactures.

[3]Data are for years ending June 30 of that stated.

TRADE

Argentina's balance of trade showed further improvement in 1977, with a trade surplus of $1.5 billion. Total exports valued f.o.b. at $5.6 billion increased 44% while imports valued (c.i.f.) at $4.1 billion increased 34%. Mineral commodities were not an important part of Argentina's international trade.

The Secretaria de Estado de Minería reported that exports of minerals and partially refined products, excluding mineral fuels and steel products, reached a record high in 1977 of $21 million, a 15% increase over that of 1976. The major export markets chiefly for nonmetals were Brazil and the United Kingdom followed by Paraguay, Italy, and the United States. The salient mineral and mineral-related exports in 1977 were steel products, $95 million; petroleum products, $25 million; boron minerals, $6.3 million; silver and tin concentrates, $3.7 million; lead ingots, $1.8 million; and uranium concentrate, $1.7 million. Exports of steel products decreased in 1977.

Nonfuel mineral imports during 1977 were valued at $803 million, a 35% decrease from those of 1975 but a 14% increase over those of 1976. Major mineral-related imports in 1977 were steel products, $360 million; crude petroleum, $298 million; refined petroleum products, $200 million; and natural gas, $89 million, mostly from Bolivia. Argentina continued to be 100% dependent on imports of metallurgical coal and

Digitized by Google

alumina for its growing steel and aluminum industries. Domestic industry also relied heavily on imports of iron ore, pig iron, and refined copper. Imports from the United States represented 19% of Argentina's total imports. The chief mineral-related U.S. imports were anthracite and bituminous coal (1.5 million tons valued at $38 million in 1977).

In October, an Argentine trade delegation visited the U.S.S.R. The Argentines agreed to Soviet participation in bidding on the Yaciretá-Apipé and Corpus electrical projects, and the Soviets expressed interest in equipment sales to the oil and coal industries of Argentina.

COMMODITY REVIEW

METALS

Aluminum.—Aluminios Argentinos S.A. (ALUAR), one of the main aluminum companies, was taken over by the military Government. The Argentine Air Force named an official trustee to run the company. By law, the Air Force supervises aluminum production in Argentina because of its important use in production of aircraft.

Kaiser Aluminum and Chemical Corp. agreed to sell its aluminum and refractory production facilities in the Buenos Aires area to a group of Argentine investors for an undisclosed amount of cash.

Argentina's first smelter, operated by ALUAR, increased its capacity from 50,000 tons to 62,500 tons per year of aluminum. Full capacity of up to 140,000 tons was expected by the revised date of 1979, with subsequent expansion to 210,000 tons by 1982.

Copper.—Compañía Minera Aguilar S.A. (CMA), a subsidiary of St. Joe Minerals Corp., continued construction of a permanent access road to the El Pachón copper ore deposit in San Juan Province. In early 1977, CMA initiated negotiations with the Government, but by yearend, no agreement had been reached covering development of the $940 million project. The Governor of San Juan Province made a grant of 1,500 hectares of land to CMA for the El Pachón mine-mill-smelter to treat the copper-molybdenum ore. The company is to set up a township for 2,500 people at Los Erizos, about 13 kilometers from El Pachón and a second township for 3,000 people at Calingasta where the smelter will be located.

CMA was waiting for the mining promotion law to finalize the legal basis of the El Pachón project before going ahead.

Yacimientos Mineros de Agua de Dionisio (YMAD) continued with its prefeasibility on the Bajo La Alumbrera copper-molybdenum-gold project that was expected to be completed in August 1978. An additional 1-year feasibility study was planned.

Iron Ore.—Construction of the offshore shiploading terminal at Punta Colorada for the Sierra Grande iron ore complex in Rio Negro Province was completed in May. The Punta Colorada terminal, built by a West German-Argentine consortium, is the first variable-orientation open-sea bulk terminal in the world. The preconcentration plant for the Sierra Grande underground mine was being constructed by a Japanese group.

In 1977, Argentina's steel industry consumed 2.4 million tons of iron ore, mostly sinter and pellets, of which 1.7 million tons were imported. It was estimated that 3 million tons of iron ore imports would be needed in 1978, probably from Brazil, Chile, and Peru.[3]

Iron and Steel.—Production of crude steel increased 11% in 1977 to a historic high of 2.7 million tons. With apparent consumption of steel estimated at 3.9 million tons, Argentina had the highest per capita consumption of steel in Latin America of 150 kilograms per person, compared with 553 kilograms per person in the United States.[4] Exports of steel products amounted to 230,000 tons valued at $95 million in 1977, compared with 356,000 tons valued at $117 million in 1976. Steel imports of 965,000 tons were valued at $360 million.

Gurmendi S.A. was planning to construct a direct reduction plant with a capacity of 400,000 tons per year of sponge iron. The $75 million plant would be located in Campana District on Río Paraná, 87 kilome-

Digitized by Google

ters northwest of Buenos Aires.

SIDERSUR was conducting feasibility studies for a $183 million direct-reduction plant in San Antonio Este, Río Negro Province, with a capacity of 410,000 tons per year planned for a 1983 startup.

As part of Argentina's national iron and steel plan, Siderúrgica Integrada S.A. (SIDINSA), created in 1975, completed the detailed engineering phase of its $3.5 billion project to construct an integrated steel complex in the coastal city of Bahía Blanca, Buenos Aires Province. The steelplant is designed to produce 3.8 million tons of steel products per year, with an eventual capacity of 8 million tons per year. By 1988, the plant would supply 50% of Argentina's demand for hot- and cold-rolled coils and sheets. The project was to be executed in four phases, the first of which was estimated to cost $720 million and was scheduled to be completed in 1983. The project was granted a Government waiver on duties on imported equipment and certain tax benefits.

During 1977, Argentina invested $222 million in the steel industry, mostly in laminated products, representing about 8% of the total investment in steel in Latin America.

Consumption of ferroalloys in 1977 increased 10% to 50,506 tons but remained below the 62,500 tons consumed in 1975.

Source: Centro de Industriales Siderúrgicos. Annual Report 1977, p. 5.

Lead and Zinc.—St. Joe reported in its 1977 annual report that output by CMA of lead-silver concentrate increased slightly to 46,707 tons and that of zinc concentrate decreased 4% to 85,723 tons. Argentina's smelter capacity was 66,000 tons per year for lead and 52,000 tons per year for zinc. According to a report of the Director Nacional de Economía Minera, Argentina in 1976 was 96% self-sufficient in zinc and 89% self-sufficient in lead.[5] Toward yearend 1977, the Government issued a decree permitting the export of 5,000 tons of electrolytic zinc or alloy through December 31, 1977.

Manganese.—Although Argentina was the second largest producer of manganese

Digitized by Google

ore in South America after Brazil, its output was relatively small. YMAD continued development of the Farallón Negro mine and plant in Catamarca Province with mine production scheduled for the revised date of mid-1978. The mine's planned annual production is 40,000 tons of 42% manganese concentrate, 19,600 troy ounces of gold, and 95,000 troy ounces of silver. In 1976, Argentina imported 67,263 tons of manganese concentrate valued at $6.3 million, of which 90% was from Brazil and the remainder from Bolivia, Australia, and India.

Molybdenum.—The most important discovery during 1977 of the Servicio Minero and DGFM was of molybdenum at Famatina in La Rioja Province. The deposit reportedly covers 35 square kilometers. Servicio Minero continued to study the prospect to obtain information needed to stimulate interest by domestic or international private mining companies. Argentina's molybdenum requirements were met by imports that in 1976 amounted to 18.6 tons. This dependency was not expected to change until the Pachón copper project comes into production.

Silver and Tin.—In late 1977, apparently large volumes of disseminated tin and associated high silver values were discovered on the property of Perquitas. Perquitas is located in La Puna District of Jujuy Province near Bolivia and is the only operating tin mine in Argentina. The inferred reserves of the deposit were estimated at 1 million tons of ore. The ore body was considered appropriate for open pit mining, and a mining and milling operation were contemplated. Argentina's measured, indicated, and inferred tin reserves were estimated at less than 30,000 tons fine tin content.

Other.—Argentina was dependent on imports for other metals considered to be of critical importance such as chromium, cobalt, mercury, nickel, platinum, and vanadium. Imports of these commodities required about $7 million per year.

NONMETALS

Boron Minerals.—Production of borates, Argentina's chief mineral export other than petroleum, increased 19% in 1977. In this same year, exports of sodium and calcium borate amounted to $6.3 million and were shipped primarily to Brazil.

Minera Simon Grandinetti Asociados S.A. was arranging for mining and processing facilities to extract borates from the Laguna de Guayatayoc 4,000 meters above sea level, in Jujuy Province. The area is located 250 kilometers from Boroquímica SAMICAF's borate operation on the edge of Salar del Hombre Muerto. The boron mineralization is largely ulexite, a hydrous sodium and calcium borate, which constitutes nearly 50% of the beds. Reserves were estimated at over 620,000 tons of ulexite with a B_2O_3 content of 30% to 35%.

Cement.—Argentina was the third largest cement producer in Latin America after Brazil and Mexico. A group of Spanish companies was studying a $76 million project to install a 625,000-ton-per-year cement plant in Salta Province to exploit a limestone deposit there. The results of the study are not yet known.

MINERAL FUELS

Coal.—Argentina continued to rely entirely on imports to meet its needs for metallurgical coal. In line with the strong increase in crude steel production, imports of metallurgical coal in 1977 increased 27% to 1.1 million tons.

State-owned Yacimientos Carboníferos Fiscales (YCF) was planning to increase production at its Río Turbio-Gallegos complex in Santa Cruz Province from 650,000 tons to 3 million tons per year by 1983. YCF awarded a contract to increase the capacity of the Río Turbio washery-coal grading plant from 500 tons (with a recovery rate ranging from 40% to 70%) to 700 tons per hour. Bids were expected to be called for a new plant with a 1,000-ton-per-hour capacity. Improvements would be required on the railroad to the Port of Río Gallegos and on the port itself, which has a handling capacity of 1 million tons per year. A degasification or briquetting plant was also under consideration.

Total reserves of subbituminous coal at Río Turbio were estimated at 550 million tons of which 285 million tons are measured reserves. Another 40 million tons of coal was reported to lie in adjacent Chilean territory.

Natural Gas.—As shown in table 5, Argentina continued to increase its production and imports of natural gas to meet the country's growing needs. In January, Argentina and Bolivia agreed to increase the price of dry gas in five quarterly increments, from $0.93 to $1.20 per thousand cubic feet by April 1978. Although natural gas and petroleum accounted for only 25% of Argentina's energy reserves, they represented 87% of the country's energy consumption in 1976. In that year, 15% of the natural gas consumed was supplied by im-

Digitized by Google

ports. Production of natural gas and petroleum represented 1.2% of the country's GDP.

Construction work continued on the new 205-kilometer gas pipeline to Cerro Redondo, Santa Cruz Province, to utilize the rich gas reserves in the National Territory of Tierra del Fuego. Completion of the gasline was scheduled for mid-1978. In 1977, the Inter-American Development Bank approved another loan of $36 million to Argentina's gas fuel agency, Gas del Estado, to expand the capacity of the southern trunk gas pipeline between Cerro Redondo and Pico Truncado from 35 million cubic meters to 48 million cubic meters per day. The additional gas would save Argentina an estimated $117 million in oil imports each year.

At yearend, Argentina's total proven gas reserves were estimated at 12 trillion cubic feet, compared with 6.7 trillion cubic feet reported for 1976.[6]

Table 5.—Argentina: Production and imports of natural gas

(Million cubic feet and U.S. dollars)

Year	Production marketed	Percent change from previous year	Imports			
			Quantity	Percent change from previous year	Value	Percent change from previous year
1973	244,376	+14	55,444	+56	18.4	+84
1974	264,859	+8	52,513	-5	29.6	+61
1975	271,639	+3	55,691	+6	43.2	+46
1976	272,288	+0	67,663	+21	66.5	+54
1977	278,000	+2	78,982	+17	89.0	+34

Petroleum.—In 1977, Argentina ranked as the third largest oil producer in Latin America after Venezuela and Mexico. Production of crude oil, first discovered in 1907 in Argentina, increased 8% but did not reach the high level of 1972, when Argentina was 94% self-sufficient. Argentina's self-sufficiency increased 2% to 88% in 1977. The State oil company YPF accounted for 76% of total crude output; YPF contracts accounted for 23% of all contracts and 1% of all concessions.[7] The Provinces of Mendoza, Chubut, and Santa Cruz were the main crude oil producers contributing 63% of the Nation's total.

In April, YPF changed its status from that of a Government dependency to that of an autonomous State enterprise.

Argentina was expanding its drilling program as a step toward its goal of gaining self-sufficiency in oil by 1985. During 1977, a total of 680 wells were drilled, compared with 503 wells in 1976. Of the total, 414 wells were capable of producing oil and 34 wells were suitable for gas production. The most significant oil discoveries in 1977 were at Ramos (San Martín Province), Huemul (Santa Cruz Province), and in Chubut Province. YPF was offering service contracts to provide for secondary recovery in the producing areas which in 1977 accounted for only 10% of total output. In October, international bidding was initiated for onshore and offshore oil exploration, especially in the zone of Tierra del Fuego. The call for bids was to expire in January 1978, and operations were to be conducted under "association contracts."

A major petrochemical complex was under development at Bahía Blanca consisting of 10 plants producing ethylene and its derivatives for industry. In 1977, the Inter-American Development Bank approved two loans totaling $105 million to Petroquímica Bahía Blanca S.A.I.C. to expand the company's capacity from 120,000 tons to 202,000 tons per year of ethylene and to help build three byproduct plants for polyethylene, polyvinyl chloride, and caustic soda.

Table 6.—Argentina: Production and trade of crude petroleum and petroleum products

(Million 42-gallon barrels and U.S. dollars)

Year	Production	Imports		Petroleum products	
		Quantity	Value	Import value	Export value
1970	143.4	10.6	31	7	44
1971	154.5	16.0	51	8	47
1972	158.5	10.9	34	5	20
1973	153.7	21.4	115	5	55
1974	151.1	21.6	343	8	101
1975	144.4	16.2	219	15	156
1976	145.6	22.1	298	18	195
1977	157.3	21.4	298	25	200

Uranium and Nuclear Energy.—Production of yellow cake (U_3O_8) increased substantially in 1977 to 1,492 tons because of the expansion of Don Otto concentration plant near the San Carlos deposit in Salta Province and the startup of the Puesto de Los Adobes plant in Chubut Province, located near the Cerro Cóndor uranium deposit. The yellow cake was further processed to 116 tons of uranium concentrate in a more advanced form. Uranium ore at Puesto de Los Adobes was estimated at 90,000 tons. As reported by the Comisión Nacional de Energía Atómica (CNEA), Argentina has proven uranium reserves of 23,785 tons U_3O_8 and potential reserves of 925,000 tons U_3O_8.

CNEA continued development of the $72 million open pit mine and plant project at Sierra Pintada, Mendoza Province. The first uranium ore from the Tigre III deposit at Sierra Pintada was delivered to CNEA's Malargüe concentration plant in December 1975. This development project was expected to be ready in 1983. Certain United States and European firms have offered to finish the feasibility study started by Siemens of Canada.

With the signing in March of the cooperation agreement with Peru, Argentina became Latin America's first exporter of nuclear energy technology. Construction continued on the civil works for CNEA's second atomic powerplant of 600-megawatt capacity at Río Tercero, Córdoba Province, by Atomic Energy of Canada Ltd. The second Candú nuclear plant was expected to be ready in 1981. By yearend, no decision had been reached on construction of the heavy-water natural uranium reactor of 685-megawatt capacity, Atucha No. 2, to be sited near the Atucha No. 1 center. By 1980 the small heavy water pilotplant at the Atucha atomic center and the new fuel production plant at the Ezeiza atomic center were expected to be ready. By 1983 Argentine industry was expected to produce an ample supply of zirconium sponge from domestic sources for the cladding of the fuel elements.

The Mineral Industry of Australia

By Charlie Wyche[1]

In 1977, the Australian mineral industry maintained a satisfactory level of performance despite depressed world demand for certain mineral commodities. Prices of some commodities declined, and there were significant stock accumulations, but output of most minerals exceeded the 1976 figures. Although world prices were at lower levels, planning and development proceeded for a number of major copper, lead, zinc, nickel, and petroleum projects in New South Wales and Western Australia. There was also considerable interest in uranium mining, and Australia could become a major world supplier of uranium oxide (U_3O_8) by 1985.

The value of mine and quarry production reached a record high of $4.5 billion,[2] an increase of nearly 10% more than the $4.1 billion reported for 1976. The $5.2 billion value added by domestic smelting and other processing of mineral commodities credited the mineral industry with products valued at $9.7 billion. This figure represents 10% of the $96 billion adjusted gross national product (GNP).

The Government provided an investment allowance, reduced the coal export levy, raised the controlled price for domestic crude oil to world parity, and provided tax concessions for offshore oil exploration. A controversial but important decision made in 1977 was to allow uranium mining to proceed. The Government also passed the Aboriginal Land Rights Act, which safeguards the territorial and cultural rights of aborigines in the uranium-rich Northern Territory.

Although the rate of inflation declined from 13.4% to 9.3% during the year, the economy remained somewhat slack, and the return of business confidence was slow. This hindered the availability of risk capital within Australia. Since a large proportion of capital used for mineral exploration in recent years has been from overseas, the level of exploration continued to increase. In 1977, private exploration expenditures totaled $134 million compared with $114 million in 1976. Nearly 50% of these expenditures were in Western Australia.

PRODUCTION

Both mine and smelter production increased for most commodities. However, depressed demand resulted in the closure or suspension of operations at some copper and nickel mines and cutbacks in planned production at manganese, phosphate, and iron ore operations. Although another gold mine closed, commencement of production at a major new mine led to an increase in domestic gold output after many years of decline. Increased production of lead resulted in a buildup of coproduct zinc stocks.

Production of mineral sands declined significantly when compared with production for recent years owing to the cessation of mining on Fraser Island and in the Double Island Point area. Prices for rutile, and especially for zircon, were also down. Significant programs of expansion and development of mines were implemented by some coal and iron ore producers.

Western Australia strengthened its position as the country's largest mineral-producing State, accounting for 38% of the

Digitized by Google

total value of mineral output in 1977. The value of minerals produced totaled $1.7 billion, a 13% increase over that of 1976, which was largely owing to increased production of iron ore, alumina, gold, coal, and crude oil. The value of iron ore shipments increased from $841 million to $951 million. The value of alumina production increased $27 million to $276 million. Values of $45.6 million for gold and $23.1 million for coal also contributed significantly to the total increased mineral value.

The value of mineral production in Queensland, the second largest mineral-producing State, totaled $1.25 billion, compared with $1.14 billion in 1976, which represented 28% of the total value of national mining sector output. Production value of certain minerals decreased slightly and increased output was recorded by others. Coal and copper, which earned $687 million and $181 million, respectively, were the principal contributors. Other significant minerals mined in Queensland were bauxite ($77 million), lead ($73 million), zinc ($67 million), silver ($52 million), and mineral sands ($17 million).

New South Wales' output of coal, lead, zinc, mineral sands, and silver ranked the State as the third largest mineral producer, with 18% of the national mining sector total value. Victoria, the only brown coal producing State, was fourth with 13%. South Australia, Tasmania, and the Northern Territory, which produced such commodities as iron ore, bauxite, tin, and copper, accounted for the remainder.

Fuel briquets	do	1,030	959	941
Gas, natural, marketed production	million cubic feet	177,491	209,380	237,596
Natural gas liquids:[10]				
Ethane	thousand 42-gallon barrels	723	961	[e]1,000
Propane	do	6,705	7,252	16,676
Butane	do	7,576	8,116	NA
Condensate	do	44	39	[e]40
Total	do	r15,048	16,368	17,716
Peat		4,800	4,449	3,197
Petroleum:				
Crude	thousand 42-gallon barrels	149,880	152,522	157,157
Refinery products:				
Gasoline:				
Aviation	do	252	297	333
Motor	do	78,220	79,960	86,875
Jet fuel	do	13,844	13,186	14,001
Kerosine	do	1,233	2,066	2,069
Distillate fuel oil	do	50,545	51,891	55,715
Residual fuel oil	do	29,820	30,704	29,380
Lubricants	do	2,440	3,358	3,573
Other:				
Refinery gas[11]	do	742	727	711
Liquefied petroleum gas	do	4,082	4,071	4,522
Solvents	do	1,258	1,455	1,472
Bitumen	do	2,830	2,911	3,340
Unspecified	do	8,680	8,389	6,756
Refinery fuel and losses	do	15,234	16,467	16,944
Total	do	209,180	215,482	225,691

[e]Estimate. [p]Preliminary. [r]Revised. NA Not available.

[1]Exports (production not officially reported).

[2]Data are for year ending November 30 of that stated for plants owned by The Broken Hill Pty. Co. Ltd.

[3]Revised to none.

[4]Western Australia only. Content of nickel ore.

[5]Excludes production from Western Australia.

[6]Data are for years ending June 30 of that stated.

[7]Excludes production from Northern Territory and Australian Capital Territory.

[8]Excludes production from Northern Territory, Australian Capital Territory, and Western Australia.

[9]Sulfur content of materials obtained as a byproduct of nonferrous metallurgical operations and oil refining.

[10]Excludes production of natural gas liquids (natural gasoline and liquefied petroleum gas) from Barrow Island, off of the Western Australian coast. An unspecified portion of the liquefied petroleum natural gas extracted is apparently marketed locally, but this quantity is limited. The bulk of the liquefied petroleum gas and all of the natural gasoline is blended with crude oil and presumably counted with crude oil from that area. Gross production of natural gas liquids on Barrow Island was as follows, in thousand barrels: liquefied petroleum gas: 1975—21,977, 1976—21,657, 1977—NA; natural gasoline: 1975—17,418, 1976—21,058, 1977—NA. Natural gas liquid output from several gasfields in Western Australia is excluded for similar reasons. Condensate production from these fields was as follows in thousand barrels: 1975—31, 1976—25, 1977—NA.

[11]Residual fuel oil equivalent.

TRADE

Increased exports and higher prices of most major minerals resulted in a record high export value. The value of exports of primary mineral products was $4.7 billion, an increase of 17% over that of 1976. For the first time in Australia's history, coal

Digitized by Google

brought more money in export earnings than wool. Australia's exports of coal were valued at $1.4 billion, iron ore and pellets at $952 million, and alumina at $629 million. Significant export values of $252 million, $231 million, and $150 million were reported for nickel, lead, and zinc, respectively.

The value of mineral imports increased to $912 million, 26% higher than in 1976. Crude oil accounted for $717 million, 79% of total mineral import value. The other principal import categories were phosphate rock, asbestos, and diamond, with values of $48 million, $34 million, and $24 million, respectively.

Table 2.—Australia: Exports and reexports of mineral commodities[1]

(Metric tons unless otherwise specified)

Commodity	1974-75	1975-76	Principal destinations, 1975-76
METALS			
Aluminum:			
Bauxite, gross weight	7,900	7,356	Japan 2,717; West Germany 2,239; Italy 1,384.
Alumina, gross weight thousand tons	4,562	5,226	NA.
Metal:			
Scrap	1,721	3,922	Japan 3,207; Netherlands 240; Taiwan 173.
Unwrought	64,065	69,074	Japan 50,330; China, People's Republic of, 5,006; Philippines 4,468.
Semimanufactures	6,128	1,631	Malaysia 336; Papua New Guinea 216; Indonesia 183.
Antimony ore and concentrates, gross weight	1,756	1,632	Belgium-Luxembourg 1,186; West Germany 173.
Beryllium ore and concentrate, gross weight	99	--	
Cadmium metal, refined, unwrought, and semimanufactures	430	604	United States 500; United Kingdom 73.
Chromium:			
Chromite ore and concentrate, gross weight	44	66	New Zealand 35; Singapore 12; Malaysia 10.
Chromium oxides and hydroxides	30	2	New Zealand 2.
Columbium and tantalum, columbite-tantalite concentrate, gross weight	123	140	Japan 67; United States 49; Netherlands 21.
Copper:			
Ore and concentrate, gross weight	146,970	161,794	Japan 155,416; Belgium-Luxembourg 2,503; West Germany 1,947.
Matte	5,849	4,909	Netherlands 3,696; Republic of South Africa 1,213.
Metal including alloys:			
Copper-lead dross and speiss	4,681	3,496	United States 3,478; Denmark 17.
Copper slags and residue	6,778	22,143	Singapore 22,121.
Scrap including alloy scrap	432	554	Japan 228; United Kingdom 152; United States 55.
Unwrought:			
Blister and cement	15,136	9,497	Japan 8,183; United Kingdom 982.
Other, unalloyed	93,862	85,801	West Germany 24,853; United Kingdom 20,733; France 12,882.
Alloyed	12	47	West Germany 36; New Zealand 4.
Semimanufactures:			
Unalloyed	16,986	14,386	New Zealand 9,241; Indonesia 1,863; Malaysia 1,433.
Alloyed	2,006	2,103	Hong Kong 954; New Zealand 364; United States 219.
Gold:			
Ore and concentrate, metal content troy ounces	[2]160,207	[2]122,462	NA.
Metal:			
Mint bullion do.	57,202	227,510	Hong Kong 154,386; West Germany 56,016; Japan 15,983.
Refined and unrefined bullion do.	95,842	5,605	New Zealand 3,530; Hong Kong 1,703; Malaysia 210.
Iron and steel:			
Ore and concentrate thousand tons	85,316	78,931	Japan 62,548; West Germany 3,399; Italy 2,198.
Roasted pyrite	130	120	Mexico 90; Thailand 18; Netherlands 12.

Dimension stone:			
Crude and partly worked	379	112	Japan 66; New Zealand 41.
Worked ____ value, thousands	$40	$58	Singapore $25; United States $18; New Zealand $10.
Sand, gravel, limestone, flux, other calcareous stone	513,856	389,700	Japan 277,768; New Zealand 48,434; United States 44,546.
Sulfur, sulfuric acid	6,101	173	Papua New Guinea 71; Fiji 46; United Arab Emirates 12.
Talc, steatite, soapstone, pyrophyllite	43,801	58,953	Japan 37,559; Netherlands 14,691; United Kingdom 4,730.
Other nonmetals, n.e.s.:			
Crude			
Quartz, mica, feldspar, fluorspar, cryolite	248	100	New Zealand 92; Japan 6.
Refractory materials, except clay and magnesite	173	340	Papua New Guinea 237; Iran 60; Fiji 19.
Other ____ value, thousands	$85	$187	Singapore $132; Japan $13; United States $8.
Oxides and hydroxides of magnesium, strontium, and barium	306	39	Philippines 36; Indonesia 1.
Building materials of asphalt, asbestos, and fiber cement ____ value, thousands	$9,887	$5,881	Canada $2,054; Bahrain $1,021; Iran $879.
MATERIAL FUELS AND RELATED MATERIALS			
Carbon black	21,180	25,814	Indonesia 8,530; New Zealand 7,824; Malaysia 4,202.
Coal, bituminous and lignite, and peat (including briquets):			
Bituminous coal and briquets ____ thousand tons	32,657	29,224	Japan 22,630; United Kingdom 2,638; France 989.
Lignite, peat, and briquets thereof	40	234	Republic of Korea 137; Nauru 93.
Coke and semicoke	420,875	181,863	West Germany 62,657; Japan 59,656; Netherlands 34,936.
Petroleum:			
Crude and partly refined thousand 42-gallon barrels	1,474	1,531	New Zealand 868; Japan 524; Singapore 139.
Refinery products:			
Gasoline ____ do	2,463	1,368	New Zealand 1,101; Fiji 120; Papua New Guinea 101.
Jet fuel ____ do	2,533	1,966	New Zealand 1,320; Fiji 281; Singapore 207.
Kerosine ____ do	635	162	New Zealand 124; Fiji 23; Papua New Guinea 10.
Distillate fuel oil ____ do	2,805	2,644	New Zealand 1,269; Singapore 534; Republic of South Africa 365.
Residual fuel oil ____ do	3,322	5,030	Japan 2,393; United States 1,815; Singapore 573.
Lubricants ____ do	730	650	New Zealand 295; Malaysia 118; Papua New Guinea 58.
Other ____ do	297	195	Mainly to New Zealand.

Table 2.—Australia: Exports and reexports of mineral commodities[1] —Continued

(Metric tons unless otherwise specified)

Commodity	1974-75	1975-76	Principal destinations, 1975-76
MATERIAL FUELS AND RELATED MATERIALS — Continued			
Mineral tar and other coal-, petroleum-, or gas-derived chemicals value, thousands	$2,685	$9,088	New Zealand $7,408; Japan $710; Belgium-Luxembourg $589.

NA Not available.

[1]Data are for years beginning July 1 and values are in Australian dollars.

[2]Australian Mineral Industry Quarterly, v. 29, No. 1 for quarters ending September and December 1975 and v. 29, Nos. 3 and 4 for quarters ending in March and June 1976 for 1975-1976 data; v. 28, No. 2 for quarters ending September and December 1974 and v. 28, No. 4 for quarters ending March and June 1975 for 1974-75 data.

[3]An unreported amount of manganese ore is included in the category "Ores and concentrates of base metals, n.e.s."

Table 3.—Australia: Imports of mineral commodities[1]

(Metric tons unless otherwise specified)

Commodity	1974-75	1975-76	Principal sources, 1975-76
METALS			
Aluminum:			
Oxide and hydroxide	9,275	4,626	Japan 2,444; United States 1,303; United Kingdom 374.
Metal including alloys:			
Scrap	1,211	1,585	New Zealand 1,442; Papua New Guinea 95; Kenya 45.
Unwrought	2,847	220	United Kingdom 205; Japan 10; United States 2.
Semimanufactures	9,414	3,977	United States 1,291; Japan 907; United Kingdom 836.
Antimony metal, all forms	203	351	China, People's Republic of, 176; Japan 160; United Kingdom 11.
Arsenic trioxide and pentoxide	1,402	537	France 174; United Kingdom 161; Sweden 116.
Beryllium metal including alloys, all forms value	$1,430	$3,000	Japan $2,000; United States $1,000.
Bismuth metal including alloys, all forms	17	6	United Kingdom 2; Bulgaria 1; Italy 1.
Cadmium metal including alloys, all forms	9	5	Belgium-Luxembourg 4; Spain 1.
Chromium:			
Chromite	39,773	4,302	Philippines 2,500; Republic of South Africa 1,802.
Oxide, hydroxide, and trioxide	879	543	U.S.S.R. 283; West Germany 160; United States 88.
Metal including alloys, all forms	28	37	Japan 25; United Kingdom 12.
Cobalt:			
Oxide and hydroxide	71	21	United Kingdom 10; Canada 10.
Metal including alloys, all forms	41	48	Belgium-Luxembourg 19; Zaire 17; United Kingdom 4.
Copper:			
Ore and concentrate kilograms	57	--	
Copper sulfate	1,090	40,871	New Zealand 40,808; United Kingdom 62; United States 1.
Metal including alloys:			
Scrap:			
Unalloyed	686	484	New Zealand 334; Papua New Guinea 121; Malaysia 16.
Alloyed	2,764	10,019	Papua New Guinea 9,710; New Zealand 250; Fiji 29.
Unwrought	258	55	New Zealand 12; United Kingdom 12; Papua New Guinea 11.
Semimanufactures value, thousands	$7,336	$4,294	United Kingdom $2,136; Japan $1,604; West Germany $233.
Gold:			
Ore and concentrate	45	2	Mostly from Fiji.
Crude bullion, gold content troy ounces	84,795	92,477	Fiji 71,646; Papua New Guinea 20,514; Hong Kong 216.
Refined bullion do	1,252	751	Switzerland 673; Singapore 37.
Iron and steel:			
Ore and concentrate, including roasted pyrite	18,378	34,038	Canada 33,983; Japan 35.
Metal:			
Scrap	492	121,118	Papua New Guinea 121,030.
Sponge iron, powder, and shot	8,702	5,004	Sweden 2,714; Japan 1,479; United Kingdom 408.
Spiegeleisen	24	12	All from West Germany.
Ferroalloys:			
Powder:			
Ferromanganese	325	88	Japan 87; United States 1.
Other	463	260	Japan 92; Republic of South Africa 90; United Kingdom 63.

Table 3.—Australia: Imports of mineral commodities[1] —Continued

(Metric tons unless otherwise specified)

Commodity	1974-75	1975-76	Principal sources, 1975-76
METALS —Continued			
Iron and steel —Continued			
Metal —Continued			
Ferroalloys —Continued			
Shot:			
Ferrochromium	9,390	4,305	Republic of South Africa 2,850; Japan 1,356; Sweden 38.
Ferromanganese	7,239	2,898	Republic of South Africa 2,405; Japan 401; West Germany 42.
Ferromolybdenum	540	109	United States 89; West Germany 13; United Kingdom 7.
Ferrosilicon	21,578	14,258	Republic of South Africa 6,674; Japan 3,880; Philippines 2,002.
Ferronickel	1,563	434	All from New Caledonia.
Other	1,697	2,648	United Kingdom 2,093; Japan 177; France 164.
Steel, primary forms	136,440	8,465	Japan 8,213; United Kingdom 111; United States 67.
Semimanufactures:			
Bars, rods, angles, shapes, sections	91,236	107,873	Japan 94,397; United Kingdom 5,762; Sweden 1,573.
Universals, plates, sheets	288,701	207,336	Japan 187,418; West Germany 9,468; United Kingdom 3,164.
Hoop and strip	40,767	24,011	Japan 18,774; United Kingdom 2,502; Sweden 975.
Rails and accessories	19,230	18,256	Japan 17,916; United Kingdom 179; U.S.S.R. 110.
Wire	63,967	8,953	Japan 5,360; United Kingdom 964; France 603.
Tubes, pipes, fittings[2]	90,335	67,436	Japan 42,245; United Kingdom 5,495; Republic of Korea 5,472.
Castings and forgings, rough value, thousands	$204	$348	United States $244; United Kingdom $85; New Zealand $6.
Lead:			
Oxides	91	19	Republic of South Africa 10; United Kingdom 7; United States 2.
Metal including alloys:			
Scrap	160	233	New Zealand 68; Papua New Guinea 29; Singapore 15.
Unwrought and semimanufactures	119	50	New Zealand 22; Canada 9; United Kingdom 5.
Magnesium metal including alloys, all forms	2,749	928	United States 486; U.S.S.R. 475; Canada 96.
Manganese:			
Ore and concentrate:			
Battery grade	2,581	1,007	All from the United States.
Metallurgical grade	171	243	United States 177.
Oxides	1,396	1,109	United States 960; Japan 114; India 33.
Metal including alloys, all forms	1,197	858	Republic of South Africa 774; France 68; Japan 16.
Mercury 76-pound flasks	1,456	1,771	China, People's Republic of, 711; Spain 531; U.S.S.R. 381.
Molybdenum:			
Ore and concentrate	642	24	Canada 19; United States 5.
Metal including alloys, all forms:			
Wire	6	7	United States 5; United Kingdom 2.
Other value, thousands	$84	$36	United States $30; United Kingdom $2.
Nickel:			
Matte, speiss, and similar materials	--	1,444	Canada 1,444.
Metal including alloys:			
Scrap	16	69	Taiwan 36; Hong Kong 22; New Zealand 11.
Unwrought	2,191	1,147	Canada 1,107; Republic of South Africa 16; Japan 14.
Semimanufactures	2,023	1,565	Japan 544; United States 503; United Kingdom 308.
Platinum-group metals and silver:			
Ore and concentrate	8	8	All from Fiji.
Waste and sweepings value, thousands	$1,132	$747	Hong Kong $458; New Zealand $174; Malaysia $62.
Metals including alloys:			
Platinum-group troy ounces	20,885	48,765	United States 27,678; United Kingdom 9,363; Netherlands 6,393.
Silver containing 75% or more silver, silver content do	38,053	32,675	Fiji 28,195; United Kingdom 3,261; West Germany 1,012.
Silicon metal	2,602	1,845	Republic of South Africa 1,512; Italy 150; Norway 61.

Table 3.—Australia: Imports of mineral commodities[1] —Continued

(Metric tons unless otherwise specified)

Commodity	1974-75	1975-76	Principal sources, 1975-76
METALS —Continued			
Tin:			
Oxides	5	9	United Kingdom 5; Netherlands 2; Japan 1.
Metals including alloys:			
Scrap	([3])	--	
Unwrought	27	41	Malaysia 32; Japan 6; China, People's Republic of, 2.
Semimanufactures	42	19	United Kingdom 11; United States 4; West Germany 2.
Tungsten:			
Ore and concentrate	--	--	
Metal including alloys, all forms	12	4	West Germany 2; United States 1; United Kingdom 1.
Other:			
Ores and concentrates:			
Of niobium, tantalum, titanium, vanadium, zirconium	11	6	All from United Kingdom.
Of base metals, n.e.s	4,726	7,550	Philippines 4,000; United States 3,201; Republic of South Africa 328.
Ash and residue containing nonferrous metals	7,683	364	New Zealand 202; Japan 128; West Germany 20.
Oxides, hydroxides, peroxides of metals, n.e.s	1,854	12,239	Japan 9,538; United Kingdom 881; United States 801.
Metals including alloys, all forms:			
Metalloids	2,668	1,707	United States 821; Japan 346; Canada 326.
Alkali, alkaline earth, and rare-earth metals	87	70	United Kingdom 50; Austria 7; Japan 5.
Base metals including alloys, all forms, n.e.s	407	63	India 15; United States 14; West Germany 13.
NONMETALS			
Abrasives, natural, n.e.s.:			
Pumice, emery, natural corundum, etc	935	492	United States 270; New Zealand 137; Italy 38.
Grinding and polishing wheels and stones	1,319	1,071	United Kingdom 184; West Germany 169; Japan 167.
Asbestos:			
Chrysotile	30,800	30,744	Canada 29,447; West Germany 880; Republic of South Africa 377.
Amosite	11,546	12,148	Republic of South Africa 11,327; Canada 597; West Germany 224.
Other	8,658	11,604	Canada 10,918; West Germany 463; China, People's Republic of, 100.
Barite and witherite, natural and ground	1,400	610	China, People's Republic of, 605; West Germany 5.
Boron materials:			
Crude natural borates	913	14	United States 13.
Oxide and acid	3,397	2,683	United States 2,681.
Cement[4]	36,839	27,770	Japan 17,433; United Kingdom 4,475; West Germany 1,888.
Chalk	10,074	8,406	United Kingdom 4,234; France 3,032; New Zealand 1,079.
Clays and clay products (including all refractory brick):			
Crude, n.e.s.:			
Bentonite	50,215	63,732	United States 63,705.
Fire clay and ball clay	4,770	10,912	United States 10,210; United Kingdom 482.
Andalusite, mullite, dinas earth, kyanite, and sillimanite	2,010	1,268	United States 1,190; Republic of South Africa 40; United Kingdom 37.
China clays including kaolin	10,028	4,941	United States 4,116; United Kingdom 825.
Other	31,526	16,625	United States 15,656;United Kingdom 312; Japan 207.
Products:			
Refractory (including nonclay brick)[5]	34,597	29,237	Japan 12,726; United Kingdom 6,086; United States 3,792.
Nonrefractory value, thousands	$24,205	$27,940	Japan $15,348; Italy $6,983; United Kingdom $1,650.
Cryolite and chiolite	193	183	All from Denmark.
Diamond:			
Gem, not set or strung metric carats	89,501	86,228	Israel 31,040; Belgium-Luxembourg 26,663; India 10,669.
Industrial, including dust do	923,761	744,655	United States 241,236; Ireland 216,084; United Kingdom 109,364.

See footnotes at end of table.

Table 3.—Australia: Imports of mineral commodities[1] —Continued

(Metric tons unless otherwise specified)

Commodity	1974-75	1975-76	Principal sources, 1975-76
NONMETALS —Continued			
Diatomite and other infusorial earth	9,895	5,821	United States 5,427; Mexico 216; Japan 142.
Feldspar, leucite, and nepheline	6,166	10,826	Norway 7,130; Canada 3,007; China, People's Republic of, 595.
Fertilizer materials:			
Crude:			
Nitrogenous	3,135	2,816	All from Chile.
Phosphatic	2,647,410	1,461,296	Nauru 642,661; Christmas Island 502,981; Gilbert and Ellice Islands 277,823.
Manufactured:			
Nitrogenous	12,288	6,510	Japan 5,167; West Germany 830; United States 147.
Phosphatic (excluding slag)	332	111	Japan 58; West Germany 32; Sweden 21.
Potassic	211,109	110,190	Canada 77,627; United States 31,044; West Germany 1,268.
Other, including mixed	4,767	4,042	West Germany 2,411; United States 726; Netherlands 406.
Ammonia value, thousands	r$1,373	$4	United States $2; United Kingdom $2.
Fluorspar	30,627	24,874	China, People's Republic of, 11,273; Republic of South Africa 9,007; Thailand 4,520.
Graphite, natural	1,269	1,289	Republic of Korea 589; China, People's Republic of, 305; Sri Lanka 191.
Gypsum and plasters	904	1,166	United Kingdom 828; United States 251; West Germany 74.
Iodine	47	46	Japan 28; United States 14; Indonesia 4.
Lime value, thousands	$37	$20	United Kingdom $10; France $6; United States $3.
Magnesite, crude, calcined, fused	174	2,604	Japan 2,500; Greece 71; United States 16.
Mica:			
Crude, including splittings and waste	888	609	Republic of South Africa 220; China, People's Republic of, 202.
Worked, including agglomerated splittings value, thousands	$410	$230	United Kingdom $70; United States $50; Switzerland $39.
Pigments, mineral:			
Natural, crude	792	1,196	United Kingdom 346; Austria 320; West Germany 295.
Iron oxides, processed	9,448	6,735	West Germany 5,495; Spain 718; United Kingdom 254.
Precious and semiprecious stones, except diamond:			
Natural value, thousands	$6,011	$10,256	Brazil $5,224; Thailand $1,267; Hong Kong $617.
Manufactured do	$468	$231	Switzerland $67; West Germany $45; Austria $34.
Salt	44,434	67,879	United Kingdom 43,884; Bahamas 23,173; Netherlands 364.
Sodium and potassium compounds, n.e.s.:			
Caustic soda value, thousands	$52,301	$5,084	NA.
Caustic potash, sodic and potassic peroxides	2,777	1,224	Japan 560; West Germany 281; India 248.
Stone, sand and gravel:			
Dimension stone:			
Crude and partly worked:			
Calcareous	3,835	2,677	Italy 2,477; Portugal 49; Greece 35.
Slate	741	712	Republic of South Africa 477; Italy 134; Portugal 56.
Other	1,610	2,791	Republic of South Africa 1,441; Canada 845; Finland 225.
Worked value, thousands	$1,329	$1,144	Italy $685; United Kingdom $102; Taiwan $95.
Dolomite	416	172	United States 127; France 12; New Zealand 8.
Gravel and crushed rock	411	255	Republic of South Africa 55; United States 46; New Zealand 42.
Limestone (except dimension)	1,591,609	1,426,467	Japan 1,385,939; New Zealand 448.
Quartz and quartzite	1,121	343	Sweden 190; West Germany 111; United States 42.
Sand, excluding metal-bearing	1,182	643	Sweden 288; New Zealand 149; United States 101.
Sulfur:			
Elemental:			
Other than colloidal	580,183	156,493	Canada 144,180; Iran 12,021; United Kingdom 167.

Commodity	1974-75	1975-76	Principal sources, 1975-76
NONMETALS —Continued			
Sulfur —Continued			
Elemental —Continued			
Colloidal	54	118	West Germany 90; United States 18; France 9.
Sulfur dioxide	369	96	Japan 89; Sweden 7.
Sulfuric acid, oleum	620	623	Japan 611; United States 11.
Talc, steatite, soapstone, and pyrophyllite	1,062	579	China, People's Republic of, 352; United States 186; Norway 23.
Vermiculite	3,639	3,496	Republic of South Africa 2,391; China, People's Republic of, 792; United States 278.
Other nonmetals, n.e.s.:			
Crude	936	1,303	France 1,129; West Germany 73; United States 32.
Slag, dross, and similar waste, not metal-bearing:			
From iron and steel manufactures	91	4	NA.
Slag and ash, n.e.s	17	64	United Kingdom 49; United States 14.
Oxides and hydroxides:			
Magnesium	21,376	9,533	Japan 9,076; United States 349.
Strontium and barium[6]	5,040	230	United States 146; Japan 58; West Germany 10.
Building materials of asphalt, asbestos and fiber cement, and unfired nonmetals, n.e.s. value, thousands	$9,887	$767	United States $255; United Kingdom $247; New Zealand $147.
MINERAL FUELS AND RELATED MATERIALS			
Asphalt and bitumen, natural	925	816	United States 576; Trinidad and Tobago 230; Argentina 10.
Carbon black	2,167	582	United States 230; West Germany 95; Canada 90.
Coal, all types, including briquets	14,230	1,389	United States 718; Japan 338; United Kingdom 332.
Coke and semicoke	17,037	1,261	United States 1,062; Norway 150; Japan 49.
Peat	5,441	30,227	West Germany 19,685; Ireland 10,276; United Kingdom 158.
Petroleum:			
Crude and partly refined thousand 42-gallon barrels	60,276	55,245	Saudi Arabia 26,263; Iran 6,542; Iraq 5,988.
Refinery products:			
Gasoline do.	2,646	4,874	Bahrain 2,106; Singapore 1,237; Republic of Korea 356.
Jet fuels do.	187	228	Singapore 198; Bahrain 26; Iran 2.
Kerosine do.	604	430	People's Democratic Republic of Yemen 203; Iran 146; Singapore 55.
Distillate fuel oil do.	3,985	3,695	Singapore 3,113; Bahrain 314; People's Democratic Republic of Yemen 208.
Residual fuel oil do.	14,906	14,165	Singapore 4,214; Bahrain 3,873; Kuwait 3,812.
Lubricants do.	565	327	Netherlands Antilles 137; United States 104; United Kingdom 43.
Other:			
Liquefied petroleum gas do.	1	1	Mainly from France and the United States.
Bitumen and other residues and bituminous mixtures, n.e.s do.	47	31	Singapore 25; United States 3; United Kingdom 1.
Petroleum coke do.	683	541	United States 427; Canada 108; Netherlands 5.
Unspecified do.	3,492	2,313	Bahrain 1,731; Iran 282; United Kingdom 101.
Mineral tar and other coal-, petroleum-, or gas-derived crude chemicals value, thousands	$4,612	$3,503	Singapore $1,992; United States $1,368; United Kingdom $86.

COMMODITY REVIEW

METALS

Aluminum.—World demand for aluminum increased during 1977, and production in Australia's aluminum industry continued the traditional upward trend. Output of bauxite, alumina, and aluminum showed increases. Advances in primary aluminum output resulted mainly from the commissioning of additional smelting capacity in mid-1977 at Bell Bay, Tasmania, by Comalco Ltd. Also, smelters at Alcoa of Australia Ltd. at Point Henry, Victoria, and of Alcan Australia Ltd. at Kurri Kurri, New South Wales, operated at full capacity throughout 1977. The record high output of alumina was owing to expanded capacity by Alcoa at Pinjarra and Kwinana in Western Australia. Full production capacity was also reported by Queensland Alumina Ltd. (QAL) at Gladstone, Queensland, and Nabalco Pty. Ltd. at Gove, Northern Territory. Higher bauxite production was reported at the three main producing areas—Weipa in Queensland, Gove in the Northern Territory, and the Darling Range, Western Australia.

Australia's total aluminum output was attributed to the full utilization of expanded capacity by Aluminum Co. of America (Alcoa). Alcoa's total output was close to the combined capacity of the Pinjarra and Kwinana refineries of 2 million and 1.4 million tons, respectively. Output from Gladstone and Gove was 2 million tons and 1 million tons, respectively.

Total production of bauxite rose about 8% above the 1976 level. At Weipa, on Cape York Peninsula, Comalco produced approximately 15% of the Western World's total bauxite supply. Comalco, which is owned 45% by Conzinc Riotinto of Australia Ltd., 45% by Kaiser Aluminum & Chemical Corp., and 10% by the Australian public, produced about 10.2 million tons of bauxite. The company shipped about 5 million tons to international markets, principally Europe and Japan. However, the largest single outlet was the Gladstone alumina refinery operated by QAL. Comalco supplied all the bauxite requirement for QAL, and, in 1977, about 52% of all bauxite shipped from Weipa was processed by QAL. Rated capacity of QAL's Gladstone refinery was 2.2 million tons annually, making it the largest alumina refinery in the world. In 1977, its production was a record high 2.1 million tons.

Rising bauxite demand has led to a 3-year development program by Comalco, with a proposed total expenditure of $81 million. This expenditure is intended to provide the facilities to permit a 12% increase in total bauxite capacity to 11.3 million tons annually. New furnaces, commissioned at Comalco's Bell Bay smelter, increased metal production capacity from 93,000 tons to 112,000 tons per year. A new casting station was also commissioned to meet the need for increased output.

Comalco's proved, probable, and possible ore reserves at the end of 1977 comprised 3.1 billion tons, with a recoverable bauxite content of 2.5 billion tons. The grade of recoverable bauxite in the 599 million tons of proved reserves ranged from 53% to 56% alumina. The alumina content in the probable reserves was in the range of 48% to 56% alumina.

Nabalco's bauxite and alumina project operated continuously throughout 1977. The plant at Gove is one of the world's largest alumina producers, with a capacity in excess of 1 million tons per year. It can readily be expanded to produce 2 million tons annually. Gove's alumina was exported to smelters in a number of countries in Western Europe, principally Norway, and in Iceland, Egypt, and the United States.

Alcoa, a fully integrated producer of bauxite, alumina, primary aluminum, and fabricated products, operated bauxite mines at Jarrahdale, Del Park, and Huntly, all in the Darling Range. Bauxite from Jarrahdale supplied a refinery at Kwinana, near Perth, and the refinery at Pinjarra used bauxite mined at Del Park and Huntly. The alumina was reduced to aluminum at the company's smelter at Point Henry.

Alcoa was planning a new refinery near Wagerup, 120 kilometers south of Perth. Construction of the 200,000-ton-per-year refinery was scheduled to start in 1978 and it was to come onstream in 1981. The design of the plant was to allow for expansion to 4 million tons per year.

The company's production of primary aluminum increased 4% in 1977 owing to the commissioning of additional smelting capacity at Bell Bay. The Alcoa and Alcan smelters operated at full capacity throughout the year. Total capacity of the three smelters was 247,000 tons annually, slightly above the 1977 output.

Digitized by Google

Exports of alumina totaled 6.1 million tons, valued at about $629 million, compared with 5.8 million tons, valued at $527 million in 1976. The average unit value of alumina exports continued to increase during the year, and at yearend it was $102.87 per ton (f.o.b.). Aluminum exports increased 20% over those of 1976. The value of exports totaled $70 million, about 55% above the 1976 value.

Copper.—Australian copper producers were faced with a worldwide buildup of stocks, rising production costs, declining consumer demand, and weakening prices during 1977. Despite these problems, domestic copper output declined only slightly (less than 1%). An increase in mine output by Mount Isa Mines Ltd. (MIM) in Queensland and by Mount Gunson Mines Pty. Ltd. in South Australia failed to offset lower production by Mount Lyell Mining & Railway Co. Ltd. in Tasmania. Production by Cobar Mines Pty. Ltd., located in New South Wales, also declined, and Gunpowder Copper Ltd. in Queensland ceased all mining operations in September 1977.

Full production was resumed in March by Samin Ltd. (Burra mine) in South Australia. Production of copper concentrate increased markedly in the second quarter, whereas previously the plant had operated at about 60% capacity.

Owing to the unfavorable economic conditions, production at several of the smelters and refineries was also down. At MIM, although mine production increased, both smelter and refinery output declined about 13% below the plant's annual capacity of 160,000 tons. At Port Kembla, New South Wales, where Electrolytic Refining and Smelting Co. of Australia Ltd. processed concentrates from Cobar and Mount Lyell, output declined. The smelter at Tennant Creek, in the North Territory, remained closed, and the mining emphasis there was on gold and the byproduct copper treated at Mount Morgan, Queensland.

The quantity of ore treated by MIM increased 12.7% (4.9 million tons) over that of 1976. About 97% of the total ore mined came from the 1100 ore body. Mining from the pillars of the 650 ore body was completed. Pillar extraction in the 650 ore body started in 1966, and this program resulted in the recovery of 2.5 million tons of ore. The recovery of pillars in the 1100 ore body reached a high degree of activity during the year and, in contrast to the program for the 650 ore body, it could continue as an integral activity of the mining program. With the 650 ore body, the pillar recovery phase occurred after the extraction of the major part of the ore body had been completed.

At MIM's Townsville copper smelter, a new $12.5 million electrostatic precipitator was commissioned with associated gas-handling equipment. Other new equipment included fume hoods on two converters, extensive instrumentation control devices, and the installation of equipment for environmental control. Output at the Townsville copper refinery declined 4.6% from that of the previous year. Power restrictions owing to industrial trouble at the Northern Electric Authority's generating station at Collinsville affected refinery production early in the year. In one 3-month period, the plant was restricted to a production rate of 90% of design capacity.

The new $4.24 million continuous rod rolling installation at Copper Refineries Pty. Ltd. (MIM subsidiary), was commissioned in September. The principal components in the line were a continuous-casting unit, which featured horizontal pouring of refined copper, and a unique new process for the rolling of cast copper bars into rods. This new development in continuous casting and rolling could result in better control of casting and greater reliability during the difficult startup operations.

Work at the MIM's Hilton mine was confined to a continuation of the underground diamond-drilling program for the confirming of ore reserves. The geological characteristics of the Hilton ore bodies are significantly different from those at Mount Isa, and more extensive information is required about them for planning purposes. The program that had been undertaken from locations on the No. 4 level was completed; and at yearend, diamond-drilling activities were being conducted from the No. 10 level.

Mount Lyell Mining & Railway Co. milled 1.8 million tons of ore and produced 70,237 tons of copper concentrates at its Queenstown, Tasmania, plant. Ore output declined 18% owing to a reduction from the two principal sources, Prince Lyell and Cape Horn. The company recorded substantial losses and received some financial assistance from Government sources to enable continued operations. The mine was the only industry in an isolated area, and any further curtailment of operations would have a serious effect on the dependent community.

Digitized by Google

Peko-Wallsend Ltd.'s copper mining operations at Tennant Creek, Northern Territory, remained closed throughout 1977. Since the closure in February 1975, due to soft copper prices and technical difficulties, studies have continued on methods to make the smelters more efficient. Some 12,600 tons of copper concentrate was produced as a byproduct of mining gold-bismuth ore at Peko-Wallsend's Warrego mine. The Warrego concentrator was expanded by the addition of a gold ore treatment plant and facilities to differentially float gold-bismuth ore. This enabled a transfer of all milling and concentrate production to Warrego with consequent greater efficiency and lower cost per ton.

Cobar Mines Pty. Ltd. treated 609,600 tons of run-of-mine copper ore to yield 30,528 tons of copper concentrate assaying 26.4% copper. The average grade of copper ore treated was 1.15% copper. Production schedules were restructured in 1977 to alleviate the adverse effects of high production costs and low prices. A target annual production rate of 600,000 tons of ore was set, and the company expected to maintain this rate for several years. Development would be restricted to that required for the open stoping areas accessible from former development. The workforce was reduced to 200 employees, but increased extraction from the more highly productive open stopes enabled ore production to exceed planned output of 600,000 tons. Copper concentrate continued to be sold under long-term contract to the Electrolytic Refining and Smelting Co.

Despite the somewhat depressed outlook for copper, base metal companies were actively exploring for new resources. Western Mining Corp. Ltd. (WMC) continued diamond drilling at the Olympic Dam prospect near Roxby Downs station in South Australia where 13 vertical holes were completed during 1977. Nine of these intersected an extensive zone of copper and uranium mineralization varying between 8 and 248 meters in thickness, with grades generally between 1.0% and 2.4% copper. The mineralized zone was encountered at about 350 meters below the surface. The holes were widely spaced over an area of 1,500 by 400 meters, but the rock type and the nature of the mineralization were similar enough to suggest continuity. Also, a joint exploration venture by WMC-BP Australia Pty. Ltd. intersected massive sulfides containing copper as well as silver-lead-zinc. The discovery was made near Benambra, Victoria, about 25 kilometers northeast of the small township of Omeo. Further drilling will be needed to determine the extent of mineralization.

Gold.—Despite closure of several mines, gold production increased 24% over that of 1976. The increase was partly owing to higher output from established producers in Western Australia, but the start of production from the Telfer Mine, also in Western Australia, had significant contribution. The Treasurer's announcement in the budget speech that the income tax exemption on production of gold would be continued was of considerable assistance to Australia's gold producers. Also, the devaluation of the Australian dollar at the end of 1976 effectively increased the Australian produc-

Digitized by Google

ers' price of gold, which helped the surviving mines.

The Telfer open pit gold project, in which Newmont Pty. Ltd. had a 70% interest and The Broken Hill Pty. Co. Ltd. (BHP), 30%, was commissioned in March. About 4.2 million tons of ore, averaging 0.28 troy ounce of gold per ton, was scheduled to be mined by open pit methods during the first 10 years. The ore was completely oxidized, and the gold occurred as discrete particles of varying sizes but mostly as fine grain. The ore was partially free milling, and up to 40% of the gold was recoverable by a gravity process. The remainder was recovered by conventional cyanide leaching. Because of the remote location of Telfer, living facilities have been constructed at the site, which is about 450 kilometers from Port Hedland.

Central Norseman Gold Corp. N.L. was the largest producer of gold in Western Australia. The company produced approximately 100,000 troy ounces in 1977. It was developing the 4 and 5 levels of the North Royal Mine, which was the main source of the gold produced. In addition, the company was designing a new open pit to mine high-grade ore near the surface. Ore reserves were estimated at 350,000 tons averaging 0.53 troy ounce of gold per ton.

The Warrego mine (formerly a copper mine), operated by Peko-Wallsend, was the only producing gold mine at Tennant Creek. The Warrego copper concentrator was modified to treat Warrego gold ore. The company was continuing to develop the Gecko copper mine, which had a comparatively low gold content.

The Blue Spec gold mine at Nullagine, Western Australia, was in production throughout 1977. The mine, operated by Australian Anglo American Ltd., experienced difficulty in reaching the expected head grade of ore; recovery of gold was below the expected figure. However, the company was actively engaged in exploration and metallurgical research work designed to overcome the problems.

Kalgoorlie Lake View Pty. Ltd. continued to operate the Mount Charlotte mine at Kalgoorlie, but the Fimiston mine remained closed. During the previous year, the company formed a partnership with Homestake Gold Ltd. to form Kalgoorlie Mining Associates. In early 1977, the partnership announced plans to place the Mount Charlotte mine on a care-and-maintenance basis because the operation was uneconomical. By midyear, however, the price of gold increased sufficiently to enable the mine to continue working. Kalgoorlie Mining Associates announced in late 1977 that it would spend up to $24 million in modernizing the treatment plant at Fimiston. As a result of the improved ore treatment facilities, which were to include the installation of a crushing section at the mine, the company expected to reduce its overall cost of production by $10 per ounce.

The principal gold producers and quantities recovered during 1977 were as follows:

Company	Production (troy ounces)
Central Norseman Gold Corp. N.L.	102,000
Kalgoorlie-Lake View Pty. Ltd	101,500
Mount Lyell Mining & Railway Co. Ltd	11,146
Peko-Wallsend Ltd	172,241

Iron and Steel.—Despite the pressure of the continued worldwide recession on demand for steel and an unprecedented number of prolonged strikes by several major Australian ore producers, the iron ore industry advanced in 1977. However, continued recession in the steel industry could create problems for Australian producers. Japanese steel mills began reducing imports within the limits of their contractural obligations. Although Australian producers did not reduce output, a buildup in stocks could force them to do so. As in recent years, most of the iron ore was produced in the Pilbara region in northwest Western Australia. In this area, five companies produced about 90% of Australia's total iron ore output: Hamersley Iron Pty. Ltd. (Mount Tom Price and Paraburdoo), Mount Newman Iron Ore Pty. Ltd. (Mount Whaleback Hill), Cliffs Western Australian Mining Co. Pty. Ltd. (Robe River), Goldsworthy Mining Ltd. (Mount Goldsworthy, Shay Gap, Sunrise Hill), and Dampier Mining Co. Ltd. (Koolan Island and Yampi Sound). Outside the Pilbara region, iron ore at Kollyanobbing was mined by Dampier for use in the Kwinana blast furnace. In South Australia, The Broken Hill Pty. Ltd. Co. (BHP) produced ore from the Middleback Ranges for steelplants in South Australia (Whyalla) and in New South Wales (Newcastle and Port Kembla). About 2 million tons of iron ore at the Savage River operation in Tasmania was slurried and pumped to a pelletizing plant at Port Latta for shipment to Japan.

The remoteness and the harsh environ-

Digitized by Google

ment of the Pilbara area created special problems for producers. In April, a severe cyclone caused costly damage to the rail link between Mount Goldsworthy and Port Hedland, and shipments to Japan were suspended for 3 weeks. Industrial strikes were fairly common in the Pilbara area and were of concern to Government, companies, and the trade unions. A major strike disrupted Mount Newman operations in June and July, and a number of smaller stoppages occurred from time to time at other mines. The Savage River operation in Tasmania was closed by a strike throughout July.

The Australian iron ore industry was almost entirely export oriented, with about 75% of exports bought by Japanese steel mills under longterm contracts. Most Japanese longterm ore contracts carry a "plus or minus" option provision under which deliveries in any one year can vary up to 10% of the contract tonnage. Although shipments declined 2 million tons, earnings were enhanced by the devaluation of the dollar and price increases applying to some contracts. This increase in earnings was partly offset by the rising costs of production. However, for most companies 1977 was more profitable than 1976.

Ore prices varied between contracting companies, as prices were negotiated by the individual exporter. Several prices applicable to the longterm contracts of Australian producers were renegotiated in 1977. Hamersley and Mount Newman, the two principal ore exporters, reached agreements with Japanese companies on ore prices. Hamersley's number one contract was for 5 million tons of ore annually. Lump ore remained at $17.74 per ton f.o.b. until April and increased to $18.43 per ton in October. Fines remained at $14.13 until September and increased to $14.76 per ton in October. The Mount Newman contract covered 7.5 million tons annually. Lump ore began the year at $16.64 per ton and increased to $18.81 per ton in October. Fines ranged from $12.88 per ton to $14.00 per ton during the corresponding period.

Production at the two mines operated by Hamersley (Mount Tom Price and Paraburdoo) declined 8% compared with the 1976 level. The decline was attributed to industrial disputes, which stopped ore production, and a drop in demand by Japanese steel producers. The company produced about 33 million tons of iron ore during the year, slightly less than the 1976 total. The principal shipping products included 16 million tons of fines, 14 million tons of lump ore, 2 million tons of pellets, and 1 million tons of low-grade ore. The largest receiver was Japan (24 million tons composed of all four products), followed by Europe (6 tons of fines and lump ore), and the United States (200,000 tons of low-grade ore). Hamersley announced plans that would increase its capacity from 40 to 46 million tons of salable ore per year. The expansion, costing about $375 million, was expected to be completed early in 1979. It involved the installation of a concentration plant to treat low-grade ore and to improve the grades and physical properties of total production. This would also enable concentrate output of suitable quality for feeding to direct-reduction steelmaking processes. In addition to heavy-media separation and wet high-intensity magnetic separation beneficiation plants, the concentrator complex included various integrated facilities.

Production by Mount Newman consortium, a joint venture operated by Mount Newman Mining, was 6% above that of 1976. The increase resulted from the company's decision to stockpile iron ore and from fewer strikes than in 1976. Mount Newman continued work on a heavy-media separation project, with estimated capital of $113 million. The facility would have an annual capacity to treat 7 million tons of lower grade iron ore to produce 5 million tons of high-grade lump and fine ore. Beneficiation would be accomplished by the gravity method.

Goldsworthy Mining's production of 6 million tons was slightly below that of 1976. Goldsworthy announced it would cease production in the Pilbara by mid-1981. With no contract in sight for its 700 million tons of Area C iron ore, Pilbara's Goldsworthy project will stop when its existing ore reserves and contracts run out. The company had only 16.3 million tons of iron ore reserves and contracts to supply 5.5 million tons annually for the next 3 years.

The principal Australian iron ore producers and their output in 1977 were as follows, in thousand tons:

Digitized by Google

Company, location, and product	Quantity
Hamersley Iron Pty. Ltd., Western Australia (lump and pellets)	33.1
Mount Newman Iron Ore Co. Mining Pty. Ltd., Western Australia (lump)	29
Goldsworthy Mining Ltd., Western Australia (lump)	6
The Broken Hill Pty. Co. Ltd. (BHP), South Australia (lump and pellets)	6
The Broken Hill Pty. Co. Ltd. (BHP) Western Australia (lump)	2

Australian reserves of iron ore were established at 35 billion tons, comprising 25.8 billion tons of hematite with 54% or more iron content, and 9.2 billion tons of limonite with 50% or more iron content. Most of Australia's reserves occur in the Pilbara region of Western Australia, which accounted for over 90% of production in 1977. New mines in the area, however, are unlikely unless iron ore prices rise substantially because none of the three planned projects is economically viable at present prices. Japanese steel mills announced that they would not take part in any new Western Australia iron ore projects until the early 1980's.

BHP remained the only steel producer in Australia, with plants at Newcastle and Port Kembla in New South Wales, Whyalla in South Australia, and Kwinana in Western Australia. Compared with 1976, total production of raw steel fell 3.5%, the lowest since 1973. Total capacity was about 9 million tons per year. Despite idle capacity, the company planned to expand capacity to follow estimated future market requirements. At many BHP facilities, expansion plans were completed or in various stages of progress. At Newcastle, major completed projects included No. 1 rod mill modifications. Work on effluent control was completed at the blast furnace and was continuing at the coke ovens. Major works completed at Port Kembla included conversion and relining of the No. 3 blast furnace. Some effluent control work was also completed at the coke ovens. Work was continuing on several other major projects including the continous slab casting and vacuum degassing plant and the uprating of No. 5 blast furnace. At Whyalla, repair work on the No. 2 blast furnace was completed. The major development still in progress was the extension on the coke ovens battery. The Geelong rod mill was commissioned in March and operated satisfactorily throughout the year. Work continued on the new coil-plate-processing line at Westernport, Victoria.

Lead and Zinc.—The improvement in the lead market was reflected by an increase in production of both commodities. Nearly all of Australia's lead and zinc was produced from deposits in which these two metals occur together in various proportions in the ore. The need to meet firm demand for lead resulted in a high level of zinc production and a buildup of stocks. Mine production of lead increased 9% above that of 1976. This increase was largely the result of increased output from Mount Isa and from two of the three mines operating at Broken Hill, but increases were also recorded at all other major mines.

Mine production of zinc increased 5% above that of 1976. The decline in output at Mineral Mining & Metallurgy Ltd.'s (MMM) Broken Hill mine and a small decrease in concentrate output at Mount Isa failed to offset substantial increases in production by Australian Mining & Smelting Co. Ltd. (AM&S) at Broken Hill and Electrolytic Zinc Co. at Read-Rosebery.

MIM remained Australia's largest single producer of lead and zinc. Again, as in 1976, 2.4 million tons of lead-zinc ore was mined, but the average grade was higher than in the previous year. Mining moved progressively deeper over the years and was concentrated between the 13 level (670 meters) and 15 level (730 meters). Although lead ore grade was higher and treatment rates comparable, the output of lead metal was restricted by environmental control actions. Lead smelter operations had to be curtailed or shutdown fairly frequently in order to maintain acceptable air quality standards at Mount Isa. To achieve the desired production levels and the appropriate environmental standards, the company decided to construct a new stack for the lead smelter together with an associated spray tower and flue system. The new stack will be 270 meters high, one of the highest structures in Australia. The estimated cost of the stack and its associated equipment is $6.7 million.

An agreement was made between the Australian Government and MIM for further exploration and study of the McArthur River zinc-lead deposit in the Northern Territory. Operation of a 50-ton-per-day pilot plant began in June to test the feasibility of commercial development. A major drilling program was also underway. MIM had conducted work at McArthur River for several years, but development was hin-

Digitized by Google

dered by metallurgical problems involved in concentrating the fine-grained ore. Sixty people were employed at the site.

Mine production by AM&S' two subsidiaries—Zinc Corp. Ltd. and New Broken Hill Consolidated Ltd. (NBHC)—was at a higher rate than that of 1976. This increase was attributed to increased ore that became available from long-hole stopes and the availability of additional experienced miners. These two factors were offset somewhat by the lower grade of ore produced. Emphasis continued to be placed on development for long-hole stoping in both Broken Hill mines, where practicable. Investigation of sand fill consolidation and of pillar mining methods aimed at improving productivity of future extraction of pillars of ore was well underway. The Zinc Corp. concentrator continued production of two grades of zinc concentrate. Many of the problems encountered earlier in retreating old mine residues were resolved, and the planned rate of concentrate production was achieved.

Because of the depressed zinc market, the Sulphide Corp. Pty. Ltd. smelter at Cockle Creek, New South Wales, continued to operate well below capacity. A more diverse range of raw materials was processed through the smelter. Development of briquet technology for recycled process materials continued successfully, with the pilot plant operating on a semicommercial basis.

The Broken Hill Associated Smelters Pty. Ltd. (BHAS) at Port Pirie, South Australia, increased both lead and zinc output over that of 1976. However, BHAS operated below capacity, largely because of strike action in April and May. Research on reflux refining of lead in collaboration with the Commonwealth Scientific Industrial Research Organization (CSIRO) was continuing. The company is committed to a pilot development process for several years.

EZ Industries Ltd.'s output from its Rosebery, Farrel, and Hercules mines varied several times during the year as a result of fluctuating market demand. Production declined to 70% of capacity early in the year and progressively increased to about 90% of capacity by June, but was substantially reduced at yearend. However, the combined output of total ore mined was 606,278 tons, 17% more than that in 1976. The increased production from the Rosebery mine was achieved mainly in the second half of the year from the introduction of an additional sublevel long-hole stope, an increase in the number of conventional stope mining parties, and an increase in development of ore. The rate of mine development increased significantly (4,013 meters at the Rosebery mine and 23 meters at the Hercules Mine, compared with a total of 2,725 meters in the previous year). The two fluid roasters treated a total of 351,779 tons of concentrate during the year.

The average grade of mine production was 12.5% zinc, 3.7% lead, and 5 troy ounces of silver per ton. Products of the concentrating mill were zinc, lead, copper, silver, gold, and pyrite concentrates, which were railed to the port of Burnie. There were 11 line-haul locomotives and 69 bulk wagons of 44-ton capacity on the railway. Traffic on the line exceeded 500,000 tons per year.

A consortium, consisting of Conzinc Riotinto of Australia and St. Joe Minerals Corp. and Phelps Dodge Corp. of the United States, began production from its $80 million open pit mine located about 65 kilometers northeast of Canberra. The operation was expected to annually produce about 1 million tons of ore, 70,000 tons of zinc, 20,000 tons of lead, 12,000 tons of copper, and 1.8 million troy ounces of silver. Output would be divided among the three joint venture partners, each of which would arrange its own sales. Diamond drilling revealed ore reserves of 10 million tons, averaging 12% zinc, 4.5% lead, 1.8% copper, and 1.8 troy ounces of silver per ton.

Table 5.—Australia: Lead-zinc production, by major company

(Metric tons)

Mine	1975		1976		1977

Manganese Ore.—Production declined substantially owing to reduced world steel output and large consumer stocks. More than 90% of the output was supplied by the Groote Eylandt Mining Co. Pty. Ltd. (GEMCO), a subsidiary of BHP, where production declined 24%.

GEMCO shipped 1.2 million tons of manganese ore from its operations in the Northern Territory. Again, the largest tonnage (610,000) went to Japan. About 270,000 tons was shipped to Europe, 150,000 tons to the United States, and 40,000 tons to the Republic of Korea. The remainder was domestically consumed and processed by the Bell Bay plant, operated by Tasmanian Electro Metallurgical Co. Pty. Ltd. (TEMCO), a subsidiary of BHP. Ferroalloy production at Bell Bay was 103,000 tons. Although this was 8% higher than last year, it was below plant capacity owing to limited demand. Following an intensive marketing program, 37,000 tons of ferroalloys was exported, compared with 5,000 tons in 1976. The effect of the world market situation for ferroalloys was reflected in the results at TEMCO, which showed a loss of $3.6 million for the year. The construction of a new 24,000-kilovolt-ampere manganese alloy furnace was nearing completion. When the expansion is completed, the plant would require about 250,000 tons of manganese ore annually, doubling the present output.

Most ore for export was sold on a contract basis, and prices were negotiated annually between buyer and seller. Japanese sources reported that prices of high-grade lump ore from Groote Eylandt increased to $65.28 per ton f.o.b. during 1977. Prices of low-grade ore reportedly remained at the $1.28 per ton unit of contained manganese f.o.b. quoted for 1976 shipments.

Australian reserves were estimated at about 890 million tons, the main part of which was on Groote Eylandt. The remainder was located principally in the east Pilbara and Peak Hill regions of Western Australia and at Pernatty Lagoon in South Australia. Known deposits in Queensland and other deposits in the Northern Territory were subeconomic. Large secondary enrichment deposits along the outcrop of the Marra Mamba iron formation in the Pilbara continued to be evaluated. These deposits were low in silica and consisted of about equal proportions of high-grade ore (40% manganese) and lower grade ores suitable for beneficiation.

Nickel.—Australia was the world's fourth largest nickel producer. Domestic production was 2% above the 1976 level. Output from major Western Australian mines increased significantly, offsetting declines at Redross and Scotia. About half of the total output came from the Kambalda Mine, operated by WMC. An additional 20% was supplied by Windara, Nepean, Redross, and Spargoville, also of Western Australia. The balance was produced at the Greenvale lateritic nickel mine in Queensland.

In 1977, WMC treated 1.5 million tons of ore and produced 292,800 tons of concentrate containing 33,340 tons of nickel. This ore included 40,159 tons purchased from the Nepean mine of Metals Exploration Ltd. At the end of 1977, WMC had eight production shafts and declines in operation. Deepening of five declines and several shaft sinkings continued during the year. The Jan shaft reached 589 meters and required an additional 38 meters for completion. It was in full production on four levels. The Edwin shaft reached 315 meters. Preparation of surface installations for the new Victor shaft was completed, and, at yearend, it had been sunk 12 meters.

In addition to operating the Kambalda and Scotia mines and managing the Windara Mine, in which it has 50% interest, WMC owns the smelter at Kalgoorlie and the refinery at Kwinana. The company treated ore and concentrates from other mines on a toll basis and also smelted the half of the Windara production owned by the Shell Co. of Australia Ltd. Annual capacity of the Kalgoorlie smelter was being expanded from 350,000 to 450,000 tons of concentrates by installing a new flash furnace and ancillary equipment. Further expansion capacity to 800,000 tons per year by the addition of oxygen to the furnace air supply was planned. The expansion was partly financed by the Agnew joint ventures for use when the Agnew project is commissioned.

Selcast Exploration Ltd. (Spargoville mine) delivered about 160,000 tons of ore to the North Kalgurli Mine Ltd. concentrator, and about 20,000 tons of concentrate containing 3,100 tons of nickel was produced. This represented an increase of about 50% above the 1976 level. The entire concentrate output was sold under contract to WMC. At Anaconda Co.-Conzinc Riotinto of Australia Ltd. (Redross mine), production declined significantly from the 27,200 tons of concentrate containing 4,100 tons of nickel pro-

Digitized by Google

duced in 1976. The Carr Boyd mine was reopened in the first quarter of 1977, but operations at both Scotia and Carr Boyd were suspended in September as a result of low nickel prices and excess supplies available on world markets.

The Greenvale mine in Queensland, owned equally by Metals Exploration and Freeport of Australia, Inc., was operated at about 80% of designed capacity during the year. The operation, which treats lateritic ore, was the first of its kind in the Southern Hemisphere and the second largest in the world. The project was more costly to establish than the sulfide counterpart, mainly because a treatment process had to be developed. Although technical problems have been largely overcome, financial difficulties have intensified, and mounting losses have thrown doubts on the future of the operation.

The joint venture for the Agnew nickel project, comprising Western Selcast Pty. Ltd. and MIM Holding Ltd., announced that arrangements were completed to enable the project to proceed to production. The facilities would initially have an annual capacity of 10,000 tons of nickel in concentrate and were expected to begin production late in 1978. The sinking of an exploration shaft would continue simultaneously with the mine construction and development work. The concentrate from Agnew would be toll smelted to matte at the Kalgoorlie smelter of WMC. In addition to the $28 million already spent, about $86 million would be required to bring the project to production.

Nickel exploration continued by several groups, mainly in Western Australia, and some small but relatively high-grade prospects were reported. At Forrestania, Western Australia, Endeavour Oil Co. N.L. announced that diamond drilling had indicated significant additions to known ore reserves at its Digger Rocks prospect. Also, Anglo American, Australian Aquitaine Petroleum Pty. Ltd., BHP, and Kennecott Copper Corp. were actively exploring the Kimberley Range of Western Australia.

Silver.—Australia is the world's sixth largest mine producer of silver. Most of the silver was a byproduct of lead-zinc mining, but some was produced as a byproduct of copper and gold mining. In 1977, mine production rose 9%, mainly because of the higher grade of ore milled at Mount Isa and by increased output by AM&S and EZ Industries. About 89% of Australia's total output came from Mount Isa in Queensland and Broken Hill in New South Wales. Most of the remainder came from Mount Lyell, Tasmania, and Tennant Creek, Northern Territory.

MIM remained Australia's largest producer of silver. Approximately 2.4 million tons of lead-zinc ore, averaging 6.8 troy ounces of silver per ton, was treated to produce approximately 10.5 million troy ounces of silver. About 85% of the silver was recovered from lead concentrate, slightly more than in 1976. In addition, silver was recovered from both zinc and copper concentrates. At Mount Isa, the lead concentrate was smelted to lead bullion, which was exported to the company's lead refinery at Northfleet, United Kingdom, where the contained silver was recovered. About 75% of the zinc concentrate was exported; the remaining 25% was shipped to the zinc refinery at Risdon, Tasmania. Silver in copper and lead residues from the electrolytic tankhouse slimes from the Townsville copper refinery were either recovered by Electrolytic Refining and Smelting Co. of Australia Ltd. at Port Kembla or were exported.

At Mount Morgan, Queensland, silver was a byproduct of open pit copper-gold mining and was recovered in blister copper. Production in 1977, including some ore from Tennant Creek, was 36,470 troy ounces of silver.

The Broken Hill area was the second greatest source of silver. Production had declined steadily in recent years because more ore was mined from the zinc-rich lodes, which contain less than 3 troy ounces of silver per ton compared with about 7 troy ounces per ton in the lead-rich ore bodies. Most of the silver produced at Broken Hill was contained in lead concentrates, which were treated at the BHAS's smelting and refining plant at Port Pirie, South Australia.

EZ Co. produced silver as a byproduct of copper-lead-zinc mining at Rosebery. In 1977, the company treated 529,158 tons of Rosebery ore, 64,312 tons of Hercules ore, and 12,800 tons of dump material. The average silver grade of the complex copper-lead-silver-gold ore treated was 4 troy ounces, 11% lower than the average grade in 1976. The ore yielded 126,948 tons of zinc concentrate containing 471,231 troy ounces of silver, 13,870 tons of lead concentrate containing 382,146 troy ounces of silver, and 25,848 tons of copper concentrate containing 1,593,064 troy ounces of silver. Lead and

Digitized by Google

copper concentrates were exported, and the silver in the zinc concentrate, which was treated at the Risdon refinery, was recovered in copper-lead-zinc residues.

About 80% of all silver exported was contained in lead bullion, lead, zinc, copper concentrates, blister copper, and various slags, mattes, and residues. The remainder was exported as refined silver and mint bullion.

Principal producers of silver and output during 1976 and 1977 were as follows, in thousand troy ounces:

Company	1976	1977
Electrolytic Zinc Co. of Australasia Ltd	2,780	2,446
Mount Isa Mines Ltd	9,450	10,484
New Broken Hill Consolidated Ltd	1,739	1,820
North Broken Hill Ltd	2,738	2,700
The Zinc Corp. Ltd	1,621	1,740

Tin.—With a year of production without export quotas, Australian mine production of tin-in-concentrate decreased 6% from that for 1976. Quotas imposed by the International Tin Council (ITC) were lifted in mid-1976, and after the ITC buffer stocks were exhausted in early 1977, the price of tin was effectively decontrolled. The tin mining companies then had extremely favorable market conditions with overall demand in excess of supply and a price increase of about 100%.

Renison Ltd., located in Renison, Tasmania, remained Australia's principal tin producer and was the world's largest tin producer from a hard-rock underground mining operation. Production of tin metal in concentrates increased from 4,010 tons to 6,300 tons. The mill treated 554,736 tons of ore with an average head grade of 1.36% tin, compared with 494,340 tons averaging 1.24% tin in 1976. The favorable 1977 output convinced company officials of the viability of its proposed tin smelter in Tasmania. With higher tin prices and greater profits, the likelihood of building the plant increased considerably. Currently, Australia has one tin smelter, which was operated by Associated Tin Smelters Pty. Ltd. (ATS). The Renison mine provided 50% of the plant's raw material. It was expected that only a slight increase in output would be necessary to supply its own smelter and ATS. Renison's proved and probable ore reserves totaled 9,895,000 tons averaging 1.24% tin; possible ore totaled 8,200,000 tons averaging 1.19% tin. The decrease in average grade of reserves resulted from the low average grade (1.05% tin) of ore newly added to reserves.

The increase in output by Renison Ltd. more than offset the decrease by the Abminco N.L. group (Cleveland Tin N.L., Aberfoyle Tin N.L., and Ardlethan Tin N.L.). At the troubled Cleveland Mine, at Luina, Tasmania, production of tin concentrate declined to 1,386 tons from 1,519 tons in 1976. The Ardlethan Mine, in New South Wales, produced 1,110 tons of concentrate, down from 1,180 tons in 1976, and output at the Rosarden and Storey's Creek mines dropped from 130 tons to 120 tons.

Minops Pty. Ltd. closed its small tin mine at Zeehan, Tasmania, because of declining ore values and recovery problems. The mine, which had a production rate of 45,000 tons per year, was operating on an ore value of 0.5% tin. A value of 0.8% was needed to make the operation profitable. In addition to the mine, the facility has a 60,000-ton-per-year treatment plant.

ATS, operating at Alexandria, New South Wales, was the only domestic producer of primary refined tin. The smelter is a joint venture of O.T. Lempriere and Co. Ltd. and Australian Iron and Steel Pty. Ltd. Production capacity of the smelter was rated at 15,000 tons annually of concentrates. However, the low average grade of concentrates available to the smelter reduced its effective output of refined tin to about 7,000 tons per year. Production of primary refined tin was 5,561 tons, 1% less than in 1976.

Titanium and Zirconium.—The world market for mineral sands concentrates was generally depressed throughout 1977, and some Australian producers ceased production. However, the demand for titanium dioxide pigment improved slightly, and Australian ilmenite producers were able to lift exports to a record 1.1 million tons despite intense competition. This, combined with a high level of domestic shipment, enabled producers to substantially liquidate large stocks that accumulated in recent years. Also, improved demand for rare-earth oxides in the United States and Europe enabled monazite exports to be increased to a record 7,530 tons, the bulk of which was shipped to France. Although output of both zircon and rutile declined, sluggishness in world industrial activity, particularly in the steel industry, was such that exports failed to match the level of production, and producer stocks of both zircon and rutile rose sharply.

Digitized by Google

There was a rash of reshuffling, production cuts, and even closures in the beach sand industry of Western Australia. Allied Eneabba Pty. Ltd. was restructured so that $11 million worth of cash and credit could be injected into the company. This was achieved through the E. I. du Pont de Nemours & Co. of the United States gaining newly issued shares in Allied Eneabba and thus increased its ownership from 25% to 40%. Reshuffling was also completed by Westralian Sands Pty. Ltd. when a majority of the shareholders agreed to a merger with Western Mineral Sands Pty. Ltd. and Ilmenite Pty. Ltd., two companies owned by the British-owned Tioxide Australia Pty. Ltd. The merger gave Tioxide a 40% share in Westralian Sands with an option to increase this to 51%.

Despite marketing and price problems, the Jennings operations at Eneabba increased production. Output of the dry plant at Geraldton finished the year with an overall 12% increase in production, from 194,924 tons to 217,690 tons. Of this total, ilmenite production went up 15% to 155,691 tons; rutile increased 8% from 36,256 tons to 39,434 tons, and zircon decreased 7% from 23,875 tons to 22,235 tons.

Dillingham-Murphyores Inc. Pty. Ltd. decided to cease all mineral sands mining in Australia. The main factor in this decision was the Federal Government's decision to ban all beach sand mining on Fraser Island, Queensland. The company claimed compensation of $23 million (as compared with the Government's offer of $4 million), stating that the Fraser Island decision reduced its reserves from a life of 20 to 5 years. A second factor in the Dillingham decision was the announcement in early 1977 by the New South Wales Government that future mining in areas designated as national parks would be banned. Dillingham officials think this would prevent it from mining most of the areas where it has leases and would severely reduce the remaining mine life of its existing operations. During 1977, Dillingham operated dry-separating plants at Cudgen and Woodburn in northern New South Wales. The Cudgen plant produced 9,800 tons of rutile and 11,900 tons of zircon from wet plants at Cudgen, Fingal, and Pottsville. The Woodburn plant produced 10,100 tons of rutile and 9,700 tons of zircon from a 650-ton-per-hour trailer-mounted mobile plant and dry-mining unit, which was relocated from Tabbimobil to Broomes Head, New South Wales.

Because of reduced prices and rising costs, mining of new ore by WMC Mineral Sands Operation, a wholly owned subsidiary of WMC, was suspended in January. Production continued from accumulated stockpiles, but in May all operations were suspended and the project put on care-and-maintenance.

The proven and probable reserves of heavy minerals totaled about 70 million tons in Western Australia, 20 million tons in Queensland, and 20 million tons in New South Wales. The grade of heavy minerals ranged from 1% near Newcastle, New South Wales, to 80% at Eneabba. All producers continued exploration, most of which was in Western Australia.

NONMETALS

Phosphate Rock.—Production increased 80% over that of 1977. Queensland Phosphate Ltd. (a wholly owned subsidiary of BH South Ltd.) developed the phosphate rock deposits at Duchess, Queensland, to operate at a capacity of 1 million tons per year. Commissioning of the treatment and train-loading facilities at the mine was completed by mid-1977, and facilities at the township were completed and occupied. Handling and ship-loading facilities in Townsville were established, and a dryer became operational in May.

Total production, averaging 31.85% P_2O_5, was located mostly in the northern sector where material was direct-shipping-grade rock. Toward the end of the year, a pit was opened in the southern sector, where resources were estimated to contain 1.5 million tons, averaging 32% P_2O_5. Exports were faced with the problem of world oversupply. Domestic fertilizer manufacturers reported that the domestic phosphate rock differed chemically and physically from the material for which their plants were designed. Sales within Australia, therefore, were restricted to small quantities for plant trials, and the manufacturers advised that necessary testing, plant modifications, and evaluation would delay the use of this material on a large scale until late 1978. This affected the company's program and contributed to serious financial problems.

A minor quantity of phosphate rock, an estimated 10,000 tons in 1977, was produced in South Australia. The material was not suitable for superphosphate manufacture because of its high iron and aluminum content, and was used locally as a fertilizer.

Australian production of phosphate fertilizer, in terms of single superphosphate

equivalent (22% P_2O_5), increased 20% in 1977.

Salt.—Salt production increased from 5.5 million tons to an estimated 6 million tons in 1977. Most of the output (85%) came from five companies, all based in Western Australia. Output from South Australia, Victoria, and Queensland accounted for the remainder. Production was by solar evaporation, mainly of sea water but also of lake and delta brines. Exports, which accounted for about 70% of the production, also varied little over the same period. The salt was sold under long-term contracts to Japanese buyers.

Companies in Western Australia (mainly Texada Mines Ltd., Dampier Salt Ltd., Leslie Salt Co., Lefroy Salt Pty. Ltd., and Shark Bay Salt Pty. Ltd.), produced 4.1 million tons of salt, valued at approximately $27 million. BHP, through its subsidiary Dampier Mining Co. Ltd., had a 76% interest in Texada Mines Ltd., one of Australia's largest producers of evaporative salt. BHP's purchase of Texada made it the first major salt exporter to have a majority Australian ownership. From one section of the field, Texada's salt came from brine that saturated the bed of Lake McLeod, the surface of which is normally dry. The lake, which is 110 kilometers long and 40 kilometers across at its widest section, is 65 kilometers north of Carnarvon. It covered an area of 225,000 hectares. The strata below the lake consisted of a layer of impure gypsum approximately 2 meters thick, underlain by halite (rock salt) varying in depth to 15 meters. The volume of halite was estimated to exceed 3 million tons.

The halite was impregnated with saturated brine that contained about 21% sodium chloride. The brine was extracted from the halite bed by large-capacity pumps and flowed to the crystallizing pan area. Approximately 25 crystallizer pans, covering an area of 800 hectares, were used for production. Each pan was harvested once a year, with salt deposited about 300 millimeters thick. Harvesting proceeded throughout the year as various pans were cleared in sequence and then refilled with brine.

Leslie Salt at Port Hedland, Western Australia, produced 1.6 million tons of salt, a slight increase over that for 1976. The workforce was increased to 88, and work was commenced to increase crystallizer capacity by approximately 20%. The company shipped to markets in the Philippines, the Republic of South Africa, Japan, Korea, New Zealand, and Taiwan.

Lefroy Salt produced about 115,000 tons of salt from its operations on Lake Lefroy. Construction of additional facilities to increase washing capacity to 500,000 tons annually was completed.

South Australia produced 560,000 tons of salt, slightly less than in 1976. The State's principal producer, Imperial Chemical Industries of Australia and New Zealand Ltd. (ICIANZ) at Dry Creek, produced about 300,000 tons. The company used the output for manufacturing sodium carbonate and sodium hydroxide. Waratah Gypsum Pty. Ltd., at Whyalla, reported production of about 85,000 tons of salt from the brines of Lake MacDonnell. The two companies accounted for about 69% of the State's output. Waratah Gypsum reported that although it had lost its export market in Southeast Asia, domestic sales had increased to more than offset these losses. BHP produced about 75,000 tons of salt from sea water at Whyalla. Salt production by Australian Salt Co. Ltd. at Lake Bumbunga and by Ocean Salt Pty. Ltd. at Price was around 20,000 tons and 50,000 tons, respectively.

Queensland produced 115,000 tons of salt during the year. The companies that contributed to the output were Central Queensland Salt Industries Ltd. (29,000 tons) and Imperial Chemical Industries Australia Ltd. (85,000 tons). Both recovered salt from naturally occurring underground brine at Bajoal, about 30 kilometers south of Rockhampton.

Sulfur.—There were no known deposits of elemental sulfur in Australia; demand for sulfur was met mainly from imports. Sulfur was consumed mainly (93%) in the form of sulfuric acid to produce fertilizer, particularly superphosphate. About 70% of sulfuric acid production was from imported brimstone and 30% from indigenous raw materials, principally zinc, pyrite, and lead concentrates. Sulfur was obtained from petroleum by Petroleum Refineries (Australia) Pty. Ltd. at Altona, Victoria, and Hallett's Cove, South Australia; Shell Refining (Australia) Pty. Ltd. at Clyde, New South Wales, and Geelong, Victoria; Australian Oil Refining Pty. Ltd. at Kernell, New South Wales; and Amoco (Australia) Pty. Ltd. at Bulwer Island, Queensland. The combined capacity of the plants was about 52,000 tons per year, but actual production depended on the sulfur content of the refinery feedstock. Output has been declining since low-sulfur Bass Strait oil began replacing high-sulfur imported crude oil. To-

Digitized by Google

tal production of sulfur from petroleum in 1977 was about 7,000 tons.

Pyrite for sulfuric acid manufacture was produced only as a byproduct of base-metal mining in Tasmania by EZ Co. and the Mount Lyell Mining & Railway Co. Ltd. The acid was produced at Burnie, Tasmania, by North-West Acid Pty. Ltd., a company jointly owned by the two pyrite producing companies. The output by North-West Acid totaled 318,074 tons of sulfuric acid in 1977, compared with 275,324 tons in 1976. The production at only about 75% of designed plant capacity was attributable to the continuation of plant operating difficulties.

Some exploration was done on pyritic black slate occurrences near Port Sorell and at Dial Range, both located in Tasmania. Tin deposits at Mount Bischoff and Renison Bell were associated with enormous deposits of pyrite and pyrrhotite and were being investigated.

MINERAL FUELS

Coal.—Domestic production of black coal was 4% above that of 1976. Expansion of the coal industry had been spectacular, and the value of exports increased tenfold since 1966. Much of this expansion was centered on large-scale and comparatively low-cost open pit mines, which accounted for about 85% of Queensland's production in 1977. In New South Wales, underground mines continued to be the main source of supply, accounting for 79% of production. Although production from New South Wales collieries accounted for about 60% of Australia's total output, more than half of the coal exported was from Queensland.

The abolition of an export coal levy was accepted in the 1976 Federal budget, and legislation was passed to phase out the charge over a 3-year period. The levy on coking coal was reduced 25% to $4.50 per ton, and the levy on inferior grades of coal was reduced from $2.00 to $1.50 per ton.

The large resources of black coal occur mainly in the Bowen Basin and West Morton district in Queensland, the Sydney Basin in New South Wales, and the Collie field, Western Australia. Outside of these areas, a small amount of black coal was produced in northern Tasmania, and subbituminous coal was produced at Leigh Creek, South Australia. Extensive deposits of lignite in Victoria were used for power generation in the Latrobe Valley and at Angelsea.

Coal produced in New South Wales was bituminous, and nearly all was mined in the Sydney Basin. More than two-thirds was high-volatile soft coking coal and steaming coal, most of which was mined in the Newcastle and Singleton areas. Smaller quantities were mined in the southern Maitland area and in the Western District around Leithgow. The low- and medium-volatile coals (premium hard-coking coals) were mined on the south coast and in the Burragorang Valley. Some high-volatile coal was mined on the north of the Sydney Basin at Gunnedah. The expansion program was vigorously maintained. To assist this expansion in New South Wales, the Government announced the construction of a $200 million coal-loading facility at Port Kembla and an extension of existing facilities in Sydney.

In Queensland, the main thrust was towards development of large deposits of coking coal for export. The Norwich Park project of Utah Development Co. (owned 89.2% by Utah International Inc. of the United States and 10.8% by Utah Mining Australia Ltd.) was started during 1977. However, work was suspended in July when the company came into conflict with the Seaman's Union over the manning of ships. The company obtained an injunction under which the union had to supply tugs until the dispute could be resolved in the Federal Court, and contract work at Norwich Park was resumed late in the year. The Hail Creek and Nebo development projects were not initiated.

The Gregory project, controlled by the BHP Co., moved a step nearer fruition when the company obtained a $1.4 billion contract to supply 27 million tons of coking coal to Japan over a period of 14 years. The mine, rail link, and port facilities at Gladstone were estimated to cost $350 million.

The Queensland Government granted exploration rights over two attractive prospects (German Creek and Oaky Creek) in the Bowen Basin. Proved resources at German Creek were 361 million tons, and planned production was on the order of 3 million tons per year from underground development. Rights were held by Capricorn Coal Development Pty. Ltd., in which the United Kingdom National Coal Board has a major interest. The Oaky Creek prospect, adjoining German Creek, was to be prospected by a partnership of Houston Oil and Minerals (80%) and R. W. Miller Holdings (20%), which was committed to spend $90 million over a period of 3 years.

The Collie field in Western Australia produced at a rate of more than 2 million

Digitized by Google

tons per year, mainly for power generation. Production was to be increased to meet anticipated higher demand.

Nearly 80% of coal exports were to Japan. Modest price rises granted on some contracts helped to maintain coal at the head of the list of mineral exports in terms of value. Other destinations included the United Kingdom, Europe, and the Republic of Korea. Export contracts were signed with Pakistan and Brazil.

Black coal reserves were estimated at 229 billion tons of which 35 billion tons was indicated and 194 billion tons was inferred. Indicated reserves were located in New South Wales (16.2 billion tons), Queensland (15.8 billion tons), Western Australia (1.9 billion tons), South Australia (730 million tons), and Tasmania (143 million tons). Substantial deposits of coal have also been delineated in areas not being mined, notably in the Surat Basin (Queensland), at Lake Phillipson in the Arckaringa Basin (South Australia), and in the Corrabin-Oaklands Basin (New South Wales).

Lignite.—Victoria produced all of Australia's lignite during 1977. The major deposits were in the Latrobe Valley, 200 kilometers southeast of Melbourne. Deposits were also located at Angelsea, Bacchus Marsh, and Gelliondale. The State Electricity Commission (SEC) produced 29.3 million tons, more than 95% of the State's total output, at Yallowin and Morwell. Coal was won by large draglines with an excavating capacity of 2,000 tons per hour. The Yallowin open pit produced at a rate of 13 million tons per year. Traditionally, production from Yallowin was used to produce a high-grade solid fuel in briquet form for domestic and industrial use. However, briquets were used as a basis for the production of high-grade char, gas, liquid fuel products, and other chemical industry feedstocks.

The Victorian Parliamentary Public Works Committee did not make a decision on the proposed Loy Yang development program, which provided for development of an open pit mine to serve a 4,000-megawatt power station. The first stage, comprising a 2,000-megawatt station, was planned to come into service between 1983 and 1988, and the second stage between 1989 and 1992.

Brown coal reserves were estimated at 122 billion tons (67 billion tons indicated and 55 billion tons inferred). Victoria had 66.7 billion tons of indicated reserves (12.2 billion tons salable), and the rest was in the Saint Vincent Basin of South Australia.

Petroleum and Natural Gas.—Crude oil production showed an increase of 3% over that of 1976. Natural gas output was 13.5% over that of 1976. The Victorian offshore fields (Bass Strait) produced 145.1 million barrels of crude oil, 92.3% of total oil production. The remainder came from Barrow Island, Western Australia, and the nearly exhausted field at Moonie, Queensland. Total oil output represented only 70% of current domestic requirements but could decline to 30% by 1985 unless significant discoveries were made and in production by that time.

Output of marketable products from Australian petroleum refineries in 1977 increased 5% compared with that of 1976. Refinery input was 294 million barrels of crude oil and other refinery feedstock. Of this total, 210 million barrels was indigenous crude.

Output of motor spirit, automotive distillate, and fuel oil increased slightly. The combined output of these three products represented 71% of the total refinery output in 1977.

Consumption of marketable petroleum products totaled 27 million barrels, an increase of 4.5% over that of 1976. Gasoline consumption of 89.7 million barrels was 7.6% over the 1976 figure. Other major products consumed were fuel oil (40 million barrels, up 3.2%), industrial diesel fuel (11.9 million barrels, up 2.5%), and aviation turbine fuel (11.7 million barrels, up 0.9%).

On the exploration and development scene, the BHP and Esso Exploration & Production Australia Inc. brought the Victoria offshore (Bass Strait) Mackerel field into production and was working on bringing onstream the Tuna (oil) and Snapper (gas) fields, also offshore Victoria. Exploration drilling by BHP-Esso resulted in the discovery of the Cobia field (Bass Strait), which would be commercially viable at import parity prices. The partnership announced the recoverable reserves in the Bass Strait fields at 2.9 million barrels of liquids and 7.2 trillion cubic feet of gas.

Overall, the exploration drilling program offshore increased from 3 wells in 1976 to 13 in 1977. Onshore, exploration wells declined from 15 to 8 in the same period. Although further development drilling will take place in the gasfields in the Roma area of Queensland and in the Cooper Basin of South Australia, most activity in the near future will be in Western Australia. There,

projects valued at many millions of dollars were expected by 1978. This upsurge was stimulated largely by the granting of permission to export gas from the Northwest Shelf, revised pricing arrangements, and tax concessions on investments in offshore exploration.

The largest single operation in Western Australia was on the Northwest Shelf, an area extending about 130 kilometers seaward and about 1,000 kilometers northeast from Barrow Island. This area includes the Rankin, Angel, and Goodwyn gas and condensate fields. A consortium comprising the BHP Co., Shell Oil Co., Woodside Petroleum Co., British Petroleum, and California Asiatic Oil Co. started a $50 million feasibility study that could lead to development. This would include construction of two production platforms, a pipeline to shore, processing and liquefaction plants, and a fleet of liquefied gas tanks, all at an estimated cost of $2.5 billion.

The initial recoverable primary and secondary reserves of crude oil were estimated to be 4 billion barrels as of June 30, 1977. The largest remaining reserves were in the offshore Gippsland Basin, amounting to 1.5 barrels, or 38% of the total. The recoverable primary and secondary reserves of natural gas on June 30, 1977, were estimated at 31 trillion cubic feet, an increase of 5% over that of 1976. This was attributed to an increase in the estimated reserves of the Northwest Shelf by the addition of the Tern and Spar Fields.

Uranium.—Mary Kathleen Uranium Ltd. (MKU), which commenced operation in 1976, remained Australia's only operating uranium mine. Production in the first half of 1977 was affected by technical problems, and a total output for the year was 420 tons of uranium oxide (U_3O_8). This quantity was inadequate to meet contract commitments, and some yellow cake (U_3O_8 concentrate) was borrowed from the government stockpile. Shipments were disrupted by a labor strike and this, together with production and marketing problems, caused a loss in excess of $15 million during the year.

The second, and final, report of the Ranger Environmental Inquiry was released in May. The 415-page report included 143 major recommendations that were applicable to a broad spectrum of issues concerning the development of the uranium industry. The principal findings and recommendations were as follows: (1) The hazards of mining and milling uranium, if those activities are properly regulated and controlled, were not such as to justify a decision not to develop Australian uranium mines; (2) the hazards involved in the ordinary operations of nuclear power reactors, if those operations were properly regulated and controlled, were not such as to justify a decision not to mine and sell Australian uranium; (3) any development of Australian uranium mines should be strictly regulated and controlled; and (4) no sales of Australian uranium should take place to any country not party to the nonproliferation treaty. Exports should be subject to the fullest and most effective safeguard agreements and be supported by fully adequate backup agreements applying to the entire civil nuclear industry in the country supplied.

In late August, the Commonwealth Government announced its decision on the mining and export of Australian uranium. The decision was that mining could proceed if and when the following conditions had been satisfied: (1) The mining operations must conform with a mandatory code of practice which the Government shall progressively prescribe; (2) the requirements of the Environmental Protection (Impact of Proposals) Act 1974 must be complied with; (3) the Government must be satisfied as to the acceptability of the development on the environment and on the Aboriginal people; and (4) uranium sale contracts must conform with the Government's safeguards policy. The announcement indicated that the Government's decision would enhance other uranium development throughout the Commonwealth, as well as in the Northern Territory.

Measured reserves in four large deposits in the Northern Territory total 297,000 tons U_3O_8 comprising Jabiluka (172,000 tons), Ranger (100,000 tons), Koongarra (15,000 tons), and Nabarlek (10,000) tons. The planned initial rate of production was 9,000 tons per year.

The Yeelirrie deposit in Western Australia has measured reserves of 46,000 tons U_3O_8, the Beverley and Mount Painter deposits in South Australia have 16,000 tons, and remaining reserves at Mary Kathleen were about 8,000 tons. This total of 367,000 tons U_3O_8 in seven deposits was considered available for immediate development. With numerous other prospects under investigation throughout the country, Australia was expected to become a major uranium producer.

The Mineral Industry of Austria

By William F. Keyes[1]

Austria's recovery from the 1975 recession, which was so hopeful in 1976, started leveling off in 1977. Industrial production was stagnant after the first quarter. Exports rose, but imports rose faster, resulting in a further growth in the foreign trade deficit to an estimated $4 billion[2] for the year.

Basic industry was especially affected by the decline. Orders for nonferrous metal manufactures and iron and steel products were about 25% below those of the previous year, and measures to introduce shorter working hours and reduce employment were underway.

Austria's mineral economy consists of fairly large-scale mining of iron ore, petroleum and natural gas, and magnesite; there is production of iron and steel, base metals, and refined petroleum products on a scale to virtually supply domestic needs. During the year, an iron blast furnace was inaugurated, work on a new lignite mine started, two major natural gas pipelines were planned, and petroleum exploration moved into a new phase of deeper drilling.

PRODUCTION

Mineral production followed the general economy and showed mixed trends. There were moderate gains in production of primary aluminum, refined copper, cement, graphite, crude magnesite, and natural gas, and moderate declines in output of iron and steel, lead, manganese, and salt.

[1]Excluding clay sand.
[2]Excluding stone used by the cement and iron and steel industries.
[3]Including blast furnace and coke oven gas. Manufactured gas is reported in source as gas having a calorific value of 4,200 calories per cubic meter.

TRADE

Austria is an importer of most major nonferrous metals and iron ore. From the United States it imports phosphate rock and clays and refractories, exchanging for these moderate but significant amounts of steel semimanufactures and some nonferrous metals. Trade with the United States in 1976 is shown in table 4.

Table 3.—Austria: Imports of mineral commodities —Continued

(Metric tons unless otherwise specified)

Commodity	1975	1976	Principal sources, 1976
Molybdenum —Continued			
Metal including alloys, all forms	570	51	Mainly from West Germany.
Nickel:			
Matte, speiss, similar materials	904	1,165	Cuba 569; United States 434; Netherlands 139.
Metal including alloys:			
Scrap	1,056	902	U.S.S.R. 505; West Germany 187; Netherlands 142.
Unwrought	1,904	2,255	Philippines 501; United Kingdom 465; Australia 306.
Semimanufactures	820	1,021	West Germany 602; United Kingdom 239; Australia 75.
Platinum-group and silver metals including alloys, all forms:			
Platinum-group troy ounces	26,331	25,946	West Germany 21,734; United Kingdom 2,379; Switzerland 1,800.
Silver:			
Bullion thousand troy ounces	5,343	6,025	West Germany 1,563; United Kingdom 1,514; Mexico 1,206.
Powder do	3	10	All from West Germany.
Semimanufactures do	8,144	3,868	West Germany 3,202; Switzerland 431.
Tin metal including alloys, all forms	479	555	West Germany 158; Thailand 158.
Titanium oxide	7,228	9,091	West Germany 5,955; Italy 1,045; United Kingdom 909.
Tungsten:			
Ore and concentrate	1,717	2,722	People's Republic of China 1,043; Australia 669; Brazil 284.
Oxide and hydroxide	204	311	NA.
Metal including alloys, all forms	196	296	West Germany 112; Republic of Korea 68; Belgium-Luxembourg 45.
Zinc:			
Ore and concentrate	128	7	NA
Oxide	504	791	West Germany 483; U.S.S.R. 170.
Metal including alloys:			
Scrap and blue powder	550	742	Belgium-Luxembourg 240; United Kingdom 203; Hungary 113.
Unwrought	7,571	5,237	West Germany 2,754; Italy 704; Bulgaria 640.
Semimanufactures	922	1,342	West Germany 1,086; Yugoslavia 130.
Other:			
Ores and concentrates	8,504	9,591	United States 4,401; Chile 1,735; West Germany 499.
Ash and residue containing nonferrous metals	69,131	81,690	U.S.S.R. 35,428; East Germany 17,735; Poland 11,877.
Waste and sweepings of precious metals kilograms	147	32,287	Mainly from West Germany.
Oxides, hydroxides, and peroxides of metals	1,493	3,344	United States 1.719; Republic of South Africa 1,312.
Base metals including alloys, all forms	4,030	1,679	U.S.S.R. 486; Belgium-Luxembourg 365; West Germany 264.
NONMETALS

COMMODITY REVIEW

METALS

Aluminum.—Capacity of the two Austrian aluminum smelters remained unchanged. Vereinigte Metallwerke Ranshofen-Berndorf AG's (VMW) capacity at Ranshofen was 80,000 tons per year, and that of Salzburger Aluminium GmbH at Lend was 12,000 tons; production was near capacity at both plants.

Exports, largely by Salzburger, and imports, largely by VMW from its subsidiary in Hamburg, Federal Republic of Germany, were both relatively moderate. In the 1970's, Austria has gone from a small net exporter of aluminum to a small net importer. This trend should be confirmed by a decision of the Renault automobile company to switch production of aluminum pressure castings from France to Austria in 1978.

Iron and Steel.—After modest growth in 1976, steel production again declined in 1977. Late in the year, utilization of crude steel capacity dropped to only about 65%; incoming orders continued to decline, and no relief was expected until the end of 1978 at least. Financial losses of the industry, including public and private sectors, were estimated at $90 million in 1977.

The nationalized sector of the steel industry, which had frequently been accused of overstaffing, continued to reduce its work force by a freeze on new hirings and voluntary retirement schemes. Late in December, these measures were supplemented by placing 15,000 workers on shorttime for at

Digitized by Google

least 3 months.

Austria had difficulty defending itself against price cuts by foreign steel producers, and imports increased from about 13% of consumption in 1974 to 25% by 1977. In November, the Government announced that it would institute a monitoring system for steel products to provide a tool by which underpriced imports could be controlled in the future through agreements with the European Coal and Steel Community and other supplier governments.

Vöest Alpine Montan AG (VAM), the Government-owned steel company that, with its subsidiaries, produces all Austrian iron ore and steel, began modernizing its managerial structure to provide greater flexibility and accountability to various activities, such as mining, metallurgy, processing, and finishing, by forming them into separate and more responsive divisions.

The year 1977 was the 25th anniversary of the introduction by VAM of the Linz-Donawitz (LD) basic oxygen steelmaking process, an Austrian development that revitalized the Austrian steel industry after World War II and then revolutionized the world industry. At the last LD international working meeting in Linz, before the patents expired, officials credited the LD process with a large part of the success of the Austrian industry in raising annual capacity to almost 5 million tons from less than 1 million tons after the war. In 1977, over 80% of Austrian steel was produced by the LD process.

VAM commissioned its new blast furnace in July, which had a capacity of 5,500 tons of steel per day; however, this represented largely replacement capacity. The bulk of planned investments in the period 1977-81, estimated to be about $1.4 billion, were, in view of market prospects, likewise earmarked for rationalization and modernization measures with little expansion of capacity.

VAM operated two integrated steel plants—one at Linz, with an annual crude steel capacity of about 3.3 million tons, and one at Donawitz, with an annual capacity of about 1.4 million tons. The Linz plant produces largely flat-rolled products; the Donawitz plant's products include billets, rods, and shapes.

Vereinigte Edelstahlwerke AG (VEW), the specialty steels producer formed in 1975, also suffered from weak markets. It was feared that the problem was structural, not cyclical, in that traditional importing countries were increasing their own capacity and carbon steels were taking over some of the market. VEW, which exported almost 80% of its output, suffered a loss of $15 million in 1976 and expected a loss again in 1977. Most of VEW's foreign customers were European countries, not developing nations.

Austria's three iron ore mines were operated by VAM. The largest, Erzberg (northwest of Leoben), contributed, from both open pit and underground, 89% of the total ore produced. There were two smaller mines—Radmer, nearby, and Hüttenberg, near Friesach in Carinthia Province. The Hüttenberg mine was reported to have only about 3 years of production life remaining.

NONMETALS

Cement.—Fifteen cement plants, with a total annual kiln capacity of 6.4 million tons, made up the Austrian industry in 1977. The largest producer was Perlmooser Zementwerke AG, with a total capacity of 2.8 million tons, including the largest Austrian plant at Mannersdorf, near Vienna, with a capacity of 1 million tons.

Salt.—A new salt evaporation plant was being constructed at Steinkogel, near Ebensee, by Österreichische Salinen AG, the nationalized salt producer. The plant will have an annual capacity of 400,000 tons of salt, produced from brines from solution mining, upon its completion in 1979.

Capacity of the Austrian salt industry in 1977 was 2 million cubic meters of brine per year from solution mines near Altaussee (where a small amount of rock salt was also produced), Hallstatt, Bad Ischl, and Hallein (Dürrnberg). Evaporation plants at Ebensee, Hallein, and Bad Aussee had a total capacity of 330,000 tons per year of salt; the mine and plants were located in the Salzkammergut, the region east and south of Salzburg. Austrian demand was about 360,000 tons annually, of which 160,000 tons was for industrial salt, 65,000 tons was for cattle and common salt, 45,000 tons was for edible salt, and 90,000 tons was for salt for road deicing.

MINERAL FUELS

The Austrian Institute for Economic Research forecast a deterioration in Austria's fuel and power situation. In the 15-year period studied, the share of domestic energy in total consumption fell from about two-thirds in the early 1960's to not much more than one-third in 1977. In this period, however, only the contribution of coal decreased

Digitized by Google

in absolute terms; oil, gas, and hydroelectric power all grew significantly. The Institute predicted a further decline in domestic energy's share to about one-fifth of total consumption in the late 1980's. It foresaw a continuation of present trends toward greater consumption of oil and gas, modest growth in hydroelectricity and nuclear electricity in spite of the high costs and environmental problems associated with them, and a decline in the relative significance of coal and lignite. Imports of both oil and gas were expected to almost double by 1990.

A revision of Austria's energy plan, projecting the supply-distribution pattern over the next 15 years, was substantially different from earlier versions in that it eliminated the two nuclear facilities that were to follow the one now nearing completion. Power companies revised their plans to emphasize conventional facilities, both thermoelectric and hydroelectric, but were uncertain of their ability to meet the country's future demands without nuclear facilities.

Austrian energy balances for 1975 and 1976 are presented in table 5.

Table 5.—Austria: Supply and apparent consumption of fuels and power

(Million tons of standard coal equivalent[1])

	Total energy	Coal and coke	Petroleum and refinery products	Natural gas	Fuelwood	Hydroelectric power
1975:						
Production	r15.8	1.7	3.0	3.3	0.9	r6.9

rRevised.
[1]1 ton standard coal equivalent (SCE)=7,000,000 kilocalories.
[2]Includes refinery and other losses and nonfuel uses.
[3]Calculated at 1,000 kilowatt-hours=0.123 tons SCE, which understates the utility of hydroelectric power.

Sources: International Energy Agency, Organization for Economic Cooperation and Development (OECD). Energy Balances of OECD Countries, 1974/1976, Paris. 1978, pp. 17-29.

Coal.—VAM exercised its option to acquire for $33.3 million an 80% interest in three mines in West Virginia's McDowell and Wyoming Counties from A. T. Massey Coal Co. Inc., a subsidiary of St. Joe Minerals Corp., in order to obtain additional metallurgical coal from a secure source. (In 1976, about 85% of Austria's coal imports came from Eastern Europe.) Total annual output from the U.S. mines was expected to approach 750,000 tons, of which VAM would be entitled to 80%.

Austrian officials conferred with Hungarian Government officials about possible joint mining of lignite deposits extending over the border. About 50 million tons are available in Austria and even larger amounts in Hungary. At the conference, it was announced that the firm Graz-Köflacher Eisenbahn und Bergbaugesellschaft (GKB) would shortly start to determine reserves in the most favorable area, around Höll and Eberau in Burgenland Province.

In October, removal of overburden started at a new open pit at GKB's Oberdorf lignite mine. Reserves were put at 33 million tons, and 1 million tons was to be produced annually after 1980. The lignite was to be delivered to a new 308-megawatt powerplant of Österreichische Draukraftwerke AG at Voitsberg, construction of which was also begun in 1977.

Austria was particularly interested in, and stood to profit by, a $200 million slurry coal pipeline that was agreed upon in principle by Poland and Italy. It would run from Katowice, Poland, to Trieste, Italy, and Austria could construct a spur from the Czechoslovak border to Linz for the supply of coal to the VAM steel mill. Other industries along the Danube River could be supplied with dried coal by barge.

Coal mines operating in Austria in 1977, all owned by nationalized concerns, are listed in the following tabulation. The

	Schmitzberg	Do	
Salzach Kohlenbergbau GmbH	Trimmelkam	Trimmelkam, Upper Austria	500

[1]Underground and open pit.

Natural Gas.—In 1977-80, the nationalized Österreichische Mineralölverwaltung AG (OMV) planned to spend $143 million for two major natural gas pipeline projects. One of these, the so-called West Austria Gas Pipeline, with an initial annual capacity of 5 billion cubic meters, was to transport Soviet gas from the Austrian-Czechoslovak border to the West German border for eventual delivery to France. The other projected pipeline, the South East Gas Pipeline, with an initial annual capacity of 800 million cubic meters, would branch off from the existing Transaustria Pipeline and would supply Yugoslavia's northern industrial zone with natural gas, also from the U.S.S.R. Both pipelines would be used to supply Austrian areas along the new transport facilities.

Petroleum.—The State-owned oil company OMV planned to counteract the recent downward trend in Austrian crude oil production by a program of deeper drilling. The country's first 7,000-meter-plus exploration well was started in November with a new, very large, and very powerful rig at Zistersdorf in the Vienna Basin where, coincidentally, Austria's first commercial production was attained before World War II; the well was expected to reach its initial target depth late in 1978.

Production to date has been from Cenozoic (10-million- to 30-million-year-old) and Mesozoic (60-million- to 160-million-year-old) formations, but indications nearby in Czechoslovakia were of possible hydrocarbons in Paleozoic (300-million-year-old) formations at the greater depth that the Zistersdorf well could reach. Previous attempts to penetrate to this depth had been frustrated by an extremely hard flysch layer.

Production in 1977 was about 12.5 million barrels of crude, a decline of about 10% from that of 1976. About 82% was from the Vienna Basin, north and northeast of Vienna, of which 62%, or 51% of the Austrian total was from the Matzen field discovered in 1949. The Molasse zone in Upper Austria Province, south of Wels, yielded the remaining 18% of the production; the most productive field continued to be that at Voitsdorf (32% of Molasse zone output).

After March 1, 1977, Austrian petroleum importers were obliged to keep on hand strategic stocks equal to 5% of the imports of the preceding year. This amount would increase 5% per year, reaching a ceiling of 20% in 1980. A total of 1.3 million tons of storage capacity will be required by 1985. The first storage capacity will be 480,000 tons at Lannach in Styria Province, and an additional capacity of 200,000 tons was planned for western Austria. Private oil firms formed a corporation, Erdöl-Lagergesellschaft mbH, to operate the facilities.

Uranium.—OMV joined the West German firm Pryssok und Co. KG in examination of the uranium occurrence at Forstau, on the border of Salzburg and Styria Provinces. Diamond drilling also continued at Tweng and Mauterndorf, two prospects near Forstau. In all, about 77 persons were employed in the exploration work in the Forstau area.

The Mineral Industry of Belgium-Luxembourg

By William F. Keyes[1]

BELGIUM

The Belgian economy was stagnant during 1977; unemployment was high, and a number of industries, particularly the steel industry, were seriously depressed. The gross national product (GNP) grew only about 2.5% in real terms, well below Government forecasts, and inflation continued at the rate of 7.1% at the wholesale level. Social costs continued to be high, and domestic and foreign markets continued weak.

Belgium had important steel and petroleum-refining industries and was a significant processor of imported copper, lead, and zinc ores, concentrates, and metals; other metals were obtained as a byproduct of the refining of these metals. The steel industry was being restructured during the year to meet the worsened outlook for its products, the policy of assisting some coal mines and closing others was continued, and the petroleum industry continued to operate at only two-thirds of capacity.

PRODUCTION

The slowdown in the economy and the mineral industry from 1976 to 1977 is illustrated by the decline in production indexes in the period: General industrial production fell from 118 to 117, extractive industries fell from 68 to 65, and steel fell from 96 to 88; only nonferrous metals improved, rising from 130 to an estimated 145. Belgium's position as a mineral processor largely dependent upon imported raw materials was clearly threatened by the rigidity of its mineral economy and the changing nature of the world mineral economy, in which processing capacity was being expanded in producing countries.

[e]Estimate. [p]Preliminary. [r]Revised. NA Not available.

[1]In addition to the commodities listed, Belgium produces a number of other metals for which only aggregate output figures are available. These aggregates are listed under "Other nonferrous metals."

[2]Known to include gold and silver and may include platinum-group metals.

[3]Derived by substracting aluminum data from a reported total for unspecified base metals.

TRADE

Belgium was a major processor of mineral raw materials, supplying both its own economy and those of its neighbors with imports from major mining countries, including Canada, Australia, and Ireland. Belgium also had significant trade with the United States; coal, sulfur, phosphate rock, and molybdenum were typical large imports, while exports to the United States included cut diamond, steel semimanufactures, and nonferrous metals. Table 4 gives a summary of Belgian-Luxembourg mineral trade with the United States.

Table 2.—Belgium-Luxembourg: Exports of mineral commodities

Fluorspar	343	840	NA.
Graphite, natural	250	508	NA.
Gypsum and plaster	47,389	78,106	Netherlands 55,467; West Germany 10,107.
Lime thousand tons	691	592	Netherlands 487.
Magnesite	1,859	3,947	France 2,794.
Mica:			
Crude, including splittings and waste	108	376	NA.
Worked, including agglomerated splittings	1,419	1,443	United States 426; West Germany 233; United Kingdom 227.
Pigments, mineral, including processed iron oxides	4,669	4,878	France 3,231; Italy 942.
Precious and semiprecious stones:			
Natural (except diamond):			
Unworked kilograms	665	117	India 60.
Worked:			
Gem do	2,020	494	West Germany 202; United States 98.
Industrial do	(1)	(1)	NA.
Manufactured[2] do	201	3,064	Netherlands 1,638; Japan 900.
Pyrite, gross weight	312	57	NA.
Salt and brine	103,992	106,011	France 88,852; Netherlands 12,084.
Sodium and potassium compounds thousand tons	214	268	NA.
Stone, sand and gravel:			
Dimension stone:			
Crude and partly worked:			
Calcareous do	871	821	Netherlands 799.
Slate do	4	3	West Germany 2.
Other do	37	42	NA.
Worked:			
Slate do	1	1	NA.
Paving and flagstone do	13	18	Netherlands 16; West Germany 2.
Other do	9	9	France 2; West Germany 2; Netherlands 2.
Dolomite, chiefly refractory grade do	1,618	1,578	Netherlands 703; West Germany 556; France 290.
Gravel and crushed rock do	9,495	10,181	Netherlands 4,832; France 4,686.
Limestone (except dimension) do	665	646	Netherlands 402; France 226.
Quartz and quartzite do	15	12	West Germany 8.
Sand, excluding metal bearing do	3,161	3,692	France 1,002; Netherlands 957; Italy 375.
Sulfur:			
Elemental, all forms	17,473	36,633	West Germany 17,379; Netherlands 12,478.
Sulfur dioxide	21	38	NA.
Sulfuric acid	106,320	74,115	France 55,440.
Talc, steatite, soapstone, pyrophyllite	15,656	21,533	West Germany 6,864; Sweden 4,164; United Kingdom 3,296.
Other:			
Crude:			
Meerschaum, amber, jet	336	90	NA.
Lithium minerals	3,685	1,390	NA.
Vermiculite, perlite, chlorite	117	46	NA.
Slag, dross, and similar waste, not metal bearing thousand tons	2,903	2,546	France 941; West Germany 808.
Oxides and hydroxides of magnesium, strontium, barium	1,805	678	NA.
Halogens, n.e.s	10	222	NA.

See footnotes at end of table.

Table 2.—Belgium-Luxembourg: Exports of mineral commodities —Continued

(Metric tons unless otherwise specified)

Commodity	1975	1976	Principal destinations, 1976
MINERAL FUELS AND RELATED MATERIALS			
Asphalt and bitumen, natural	5,860	8,092	Netherlands 5,083.
Carbon black and gas carbon:			
Carbon black	11,841	978	France 431; Netherlands 215; West Germany 124.
Gas carbon	31	34	NA.
Coal and briquets:			
Anthracite and bituminous coal thousand tons	542	378	West Germany 258; Netherlands 44.
Briquets of anthracite and bituminous coal do	20	13	France 7; Switzerland 3.
Coke and semicoke do	360	317	United States 102; France 65; West Germany 58.
Gas, natural million cubic feet	r424	360	Mainly to Netherlands.
Hydrogen, argon, other rare gases	13,258	17,220	France 7,252; West Germany 5,656.
Peat, including briquets and litter	859	751	NA.
Petroleum:			
Crude and partly refined thousand 42-gallon barrels	571	9	NA.
Refinery products:[3]			
Gasoline do	25,336	13,409	West Germany 3,849; Denmark 1,861; Netherlands 1,757.
Kerosine do	5,715	4,740	West Germany 1,937; Denmark 770.
Distillate fuel oil do	20,711	36,468	West Germany 13,425; Denmark 4,691.
Residual fuel oil do	31,377	35,924	United Kingdom 7,313.
Lubricants do	2,039	2,091	Netherlands 713; West Germany 246.
Other:			
Liquefied petroleum gas do	1,707	1,868	Netherlands 882; United States 499.
White spirit do	1,269	792	West Germany 352; Netherlands 139.
Mineral jelly and wax do	13	30	United Kingdom 8; France 5; Spain 4.
Nonlubricating oils, n.e.s do	7,079	5,674	Netherlands 1,993; West Germany 1,382.
Bitumen and other residues do	1,800	1,303	Netherlands 545; West Germany 321; United Kingdom 164.
Bituminous mixtures, n.e.s do	75	133	Netherlands 97; France 24.
Pitch, pitch coke, petroleum coke do	31	215	Netherlands 193.
Mineral tar and other coal-, petroleum-, or gas-derived crude chemicals thousand tons	211	252	Netherlands 103; France 42; West Germany 39.

rRevised. NA Not available.
[1]Less than 1/2 unit.
[2]May include diamond.
[3]Includes bunkers.

Table 3.—Belgium-Luxembourg: Imports of mineral commodities

(Metric tons unless otherwise specified)

Commodity	1975	1976	Principal sources, 1976
METALS			
Aluminum:			
Bauxite and concentrate	16,380	19,680	Guyana 9,061; Denmark 6,022; West Germany 2,168.
Oxide and hydroxide	12,689	21,057	West Germany 14,629; France 2,931.
Ash and residue containing aluminum	758	1,336	West Germany 1,182.
Metal including alloys:			
Scrap	14,778	19,073	West Germany 6,414; France 5,102; Netherlands 4,449.
Unwrought	188,176	258,248	Netherlands 106,826; Norway 42,403; West Germany 39,507; France 33,200.
Semimanufactures	52,140	79,670	West Germany 37,270; Netherlands 19,956; France 9,773.
Antimony:			
Ore and concentrate	8,707	11,170	Bolivia 4,658; Guatemala 1,382.
Metal including alloys, all forms	222	210	NA.
Arsenic:			
Natural sulfides	53	1	NA.
Trioxides, pentoxides, and acids	121	44	NA.
Beryllium metal including alloys, all forms kilograms	300	100	NA.
Cadmium metal including alloys, all forms	978	1,376	Japan 415; West Germany 248; Zaire 158.
Chromium:			
Chromite	3,714	2,776	Republic of South Africa 1,353; Netherlands 629; Mozambique 231.
Oxide and hydroxide	555	2,120	Japan 1,349; West Germany 382.
Metal including alloys, all forms	232	145	West Germany 71; United Kingdom 56.

Table 3.—Belgium-Luxembourg: Imports of mineral commodities —Continued

(Metric tons unless otherwise specified)

Commodity	1975	1976	Principal sources, 1976
METALS —Continued			
Cobalt oxides and hydroxides ____ kilograms	20,600	65,500	West Germany 37,500; Netherlands 18,000.
Copper:			
Ore and concentrate	46,651	24,053	Chile 10,463; Australia 3,975; Morocco 3,047; Bolivia 2,592.
Matte	214,471	229,932	Zaire 141,227; Republic of South Africa 43,958.
Copper sulfate	1,084	2,257	U.S.S.R. 1,048; France 757.
Ash and residue containing copper	38,970	21,806	Chile 10,463; France 5,480; United States 5,018.
Metal including alloys:			
Scrap	58,545	82,098	France 35,383; Netherlands 14,566; United States 8,942.
Unwrought	190,656	307,789	Zaire 192,096.
Semimanufactures	25,768	36,643	West Germany 17,161; France 6,317; Netherlands 4,221.
Gold:			
Waste and sweepings ___ value, thousands	$610	$2,514	United States $2,100.
Metal, worked and partly worked thousand troy ounces	2,623	1,411	West Germany 1,292.
Iron and steel:			
Ore and concentrate, except roasted pyrite thousand tons	25,520	25,593	France 11,896; Sweden 4,129.
Roasted pyrite ____ do	214	233	France 115; West Germany 77; Sweden 25.
Metal:			
Scrap ____ do	706	586	France 226; Netherlands 139; West Germany 120.
Pig iron, including cast iron ____ do	161	203	West Germany 80; France 56; Brazil 44.
Sponge iron, powder, shot ____ do	6	6	France 2; West Germany 2.
Spiegeleisen ____ do	(1)	(1)	NA.
Ferroalloys ____ do	153	197	Norway 55; France 49; West Germany 28.
Steel, primary forms ____ do	810	1,143	Netherlands 297; West Germany 264; East Germany 137; France 128.
Semimanufactures:			
Bars, rods, angles, shapes, sections do	734	926	France 332; West Germany 167.
Universals, plates, sheets ____ do	520	781	Japan 172; West Germany 127; Netherlands 111; Spain 86.
Hoop and strip ____ do	100	114	France 61; West Germany 35.
Rails and accessories ____ do	11	31	France 27.
Wire ____ do	40	57	West Germany 24; France 15; Netherlands 6.
Tubes, pipes, fittings ____ do	192	163	West Germany 50; France 38; Netherlands 35.
Castings and forgings, rough ____ do	22	35	France 16; West Germany 6; Netherlands 3.
Lead:			
Ore and concentrate	90,268	132,588	Peru 48,558; Canada 18,511.
Ash and residue containing lead	63,015	61,217	France 15,655; West Germany 13,810; United States 12,529.
Oxides	843	1,959	France 923; West Germany 830.
Metal including alloys:			
Scrap	12,439	9,619	West Germany 4,837; Netherlands 3,791.
Unwrought	13,857	33,382	France 14,600; Australia 9,464; United Kingdom 4,389.
Semimanufactures	2,074	1,546	Netherlands 707; West Germany 444; France 158.
Magnesium metal including alloys:			
Scrap	153	209	Netherlands 73; West Germany 59.
Unwrought	1,207	1,232	Italy 394; Norway 252; France 247; U.S.S.R. 158.
Semimanufactures	183	131	United States 29; France 28.
Manganese:			
Ore and concentrate	313,264	328,968	Republic of South Africa 140,392; Ghana 56,777.
Oxides	1,275	1,634	Japan 1,349.
Metal	615	572	Republic of South Africa 235; West Germany 71.
Mercury ____ 76-pound flasks	8,963	2,009	United Kingdom 870; Netherlands 290.
Molybdenum:			
Ore and concentrate	13,175	11,909	Canada 4,174; United States 3,714; Chile 2,450.
Metal including alloys, all forms	77	110	Netherlands 61; France 20.
Nickel:			
Matte, speiss, similar materials	87	83	United Kingdom 38; Australia 18; Canada 11.
Metal including alloys:			
Scrap	1,060	1,172	France 330; United Kingdom 246; Netherlands 146.
Unwrought	3,495	3,439	United Kingdom 611; Cuba 573; Canada 467; France 446; Republic of South Africa 408.
Semimanufactures	3,316	4,802	West Germany 2,540; France 1,229.

Table 3.—Belgium-Luxembourg: Imports of mineral commodities —Continued

(Metric tons unless otherwise specified)

Commodity	1975	1976	Principal sources, 1976
METALS —Continued			
Platinum-group metals including alloys, all forms, troy ounces	292,539	7,365,629	United States 6,812,669.
Selenium, elemental, kilograms	42,300	21,500	Netherlands 5,700; West Germany 4,600; Japan 2,000.
Silver metal including alloys, thousand troy ounces	18,711	21,190	Netherlands 8,914; United States 5,272.
Tin:			
Ore and concentrate	7,210	5,173	Zaire 3,764; Rwanda 1,221.
Oxides	40	35	West Germany 28; Italy 6.
Metal including alloys:			
Scrap	113	214	Netherlands 151.
Unwrought	1,756	2,507	Malaysia 852; Zaire 704; Netherlands 365; United Kingdom 279.
Semimanufactures	300	240	Netherlands 112; West Germany 79; France 29.
Titanium:			
Ore and concentrate	31,350	101,941	Canada 100,999.
Oxides	10,522	11,726	West Germany 4,618; Netherlands 2,951; France 1,451; United States 1,257.
Metal including alloys, all forms	1,598	1,659	United States 1,375.
Tungsten:			
Ore and concentrate	375	454	West Germany 143; Netherlands 86; Zaire 83; People's Republic of China 46.
Metal including alloys, all forms	157	165	Netherlands 85; France 26; United Kingdom 23.
Uranium metal including alloys, all forms, value, thousands	$50,267	$77,004	United Kingdom $76,114.
Zinc:			
Ore and concentrate	610,984	549,982	Canada 349,877.
Oxide and peroxide	7,548	9,217	France 2,696; United Kingdom 2,299; Netherlands 2,021.
Ash and residue containing zinc	71,610	62,736	France 21,546; West Germany 20,410; United States 6,777.
Metal including alloys:			
Scrap	14,330	8,316	France 2,466; Netherlands 1,986; United States 1,342; West Germany 1,168.
Blue powder	784	862	West Germany 409; Italy 152; Netherlands 141; France 97.
Unwrought	23,885	29,051	Netherlands 8,031; North Korea 3,556.
Semimanufactures	9,167	9,863	France 8,636.
Other:			
Ores and concentrates:			
Of niobium, tantalum, vanadium, zirconium	1,002	1,710	Canada 671; Netherlands 278; United States 246.
Of precious metals	241	574	Bolivia 447; Colombia 127.
Of base metals, n.e.s	475	646	Netherlands 354.
Ash and residue containing nonferrous metals, n.e.s	33,993	42,004	West Germany 28,831; Republic of South Africa 4,634.
Waste and sweepings of precious metals, value, thousands	$17,209	$9,587	United States $4,226; France $2,446; Netherlands $1,820.
Oxides, hydroxides, peroxides of metals, n.e.s	1,936	2,014	West Germany 842; Republic of South Africa 295; France 223.
Metals including alloys, all forms:			
Metalloids:			
Tellurium and arsenic	69	77	Sweden 45; U.S.S.R. 14.
Other	440	434	France 166; West Germany 108; United States 75.
Alkali, alkaline-earth, rare-earth metals	49	150	U.S.S.R. 50; West Germany 35; Brazil 28; France 20.
Pyrophoric alloys	3	3	NA.
Base metals including alloys, all forms, n.e.s	75	159	United States 54.
NONMETALS			
Abrasives, natural, n.e.s.:			
Pumice, emery, natural corundum, etc	90,427	77,335	West Germany 76,392.
Dust and powder of precious and semiprecious stones, natural and manufactured, including diamond, kilograms	1,974	3,016	Ireland 1,485; United States 1,141.
Grinding and polishing wheels and stones	2,533	2,506	West Germany 733; Netherlands 386; France 260.
Asbestos	60,549	70,370	Canada 32,351; U.S.S.R. 19,626; Republic of South Africa 9,383.
Barite and witherite	7,829	8,477	France 5,170; West Germany 2,975.
Boron materials:			
Crude material borates	49,838	60,637	Netherlands 36,725; Turkey 22,155.
Oxide and acid	1,495	1,952	France 1,448.
Bromine, kilograms	46,100	26,800	NA.
Cement	76,328	96,656	Netherlands 61,513; France 11,241.

See footnotes at end of table.

Table 3.—Belgium-Luxembourg: Imports of mineral commodities —Continued

(Metric tons unless otherwise specified)

Commodity	1975	1976	Principal sources, 1976
NONMETALS —Continued			
Clays and clay products:			
Crude:			
Bentonite	22,654	27,822	West Germany 10,516; Netherlands 6,996; United States 6,187.
Kaolin	237,206	252,834	United Kingdom 87,739; Netherlands 56,612; West Germany 28,907.
Other	198,853	226,611	West Germany 131,021; France 34,779; Netherlands 29,875.
Products:			
Refractory (including nonclay brick)	108,054	97,228	West Germany 50,197.
Nonrefractory value, thousands	$75,742	$89,457	West Germany $28,379; Italy $23,140; Netherlands $17,328.
Cryolite and chiolite	112	114	NA.
Diamond (except powder):			
Gem:			
Unworked thousand carats	12,535	19,753	United Kingdom 16,825.
Worked do	1,279	1,692	India 519; Israel 253; U.S.S.R. 245.
Industrial:			
Unworked do	7,772	9,384	Ireland 3,500; United States 1,727; United Kingdom 1,394; Canada 1,183.
Worked do	7	9	United Kingdom 5; West Germany 1.
Diatomite and other infusorial earth	7,403	6,341	France 2,564; Denmark 2,025.
Feldspar, leucite, nepheline, nepheline syenite	61,532	66,232	Norway 38,517; France 19,333.
Fertilizer materials:			
Crude:			
Nitrogenous	12,464	18,726	Chile 17,404.
Phosphatic thousand tons	1,771	1,582	Morocco 1,088.
Potassic	1,286,227	9,831	West Germany 5,564; France 4,267.
Manufactured:			
Nitrogenous (N_2 content)	10,213,191	148,365	France 29,670; West Germany 29,580; Netherlands 26,261.
Phosphatic (P_2O_5 content)	1,320,278	36,071	United States 8,171; Tunisia 5,304; Netherlands 4,085.
Potassic	53,255,196	486,528	West Germany 167,955; France 158,477; U.S.S.R. 101,944.
Other, including mixed	122,643	215,418	France 49,639; United States 46,715; West Germany 24,987.
Ammonia	1,499	2,043	West Germany 1,237; Netherlands 490.
Fluorspar	10,101	16,203	France 6,927; People's Republic of China 5,013; West Germany 2,909.
Graphite, natural	1,915	1,068	West Germany 346; Madagascar 300; United Kingdom 118.
Gypsum and plasters	470,371	473,300	France 446,010.
Lime	107,573	212,965	France 139,864; West Germany 66,355.
Magnesite	25,940	28,310	Greece 14,755; Czechoslovakia 3,398; Netherlands 3,307.
Mica:			
Crude, including splittings and waste	7,034	2,034	India 476; United Kingdom 426; France 423; Madagascar 255.
Worked, including agglomerated splittings	38	62	West Germany 32; Switzerland 15.
Pigments, mineral, including processed iron oxides	6,104	7,706	West Germany 6,255.
Precious and semiprecious stones, except diamond:			
Natural:			
Unworked kilograms	9,543	6,521	West Germany 3,638; Zambia 1,370.
Worked:			
Gem do	1,449	1,687	West Germany 746; Netherlands 150.
Industrial do	42	11	NA.
Manufactured do	3,816	2,123	United States 697.
Pyrite, gross weight	207,810	220,452	Spain 220,272.
Salt and brine thousand tons	796	935	Netherlands 481; West Germany 426.
Sodium and potassium compounds, n.e.s	44,605	25,833	West Germany 11,321; United Kingdom 9,018.
Stone, sand and gravel:			
Dimension stone:			
Crude and partly worked	155,295	169,113	France 43,829; West Germany 40,167.
Worked	67,655	73,745	Italy 22,655; France 18,037; West Germany 8,177.
Dolomite, chiefly refractory grade	74,991	93,571	West Germany 62,444; France 24,070.
Gravel and crushed rock thousand tons	5,249	5,768	Netherlands 2,704; United Kingdom 1,315; West Germany 970.
Limestone (except dimension)	281,893	307,420	United Kingdom 206,646; France 12,459.
Quartz and quartzite	115,822	110,630	West Germany 18,512; Norway 12,459.
Sand, excluding metal bearing thousand tons	8,959	11,139	Netherlands 9,996.
Sulfur:			
Elemental, all forms	441,676	461,510	United States 349,655.
Sulfur dioxide	4,182	6,708	West Germany 6,166.
Sulfuric acid	162,263	178,792	West Germany 82,401; France 42,304; Netherlands 30,946.
Talc, steatite, soapstone, pyrophyllite	23,403	39,026	United States 18,791; Australia 6,751; France 4,025.

COMMODITY REVIEW

Metals.—*Aluminum.*—Belgium produced no primary aluminum. Large quantities of ingot were imported from other members of the European Economic Community (EEC), especially the Netherlands, and Belgium together with the Federal Republic of Germany were the largest exporters of semimanufactured aluminum in the EEC. About 80% of aluminum semimanufactures is exported, of which two-thirds goes to other members of the EEC.

Output of rolled aluminum products increased significantly in 1977 as a result of the 1976 startup by Soc. Industrielle de l'Aluminium S.A. (SIDAL) of a new rolling mill at Duffel, south of Antwerp.

Lead-Zinc.—Métallurgie Hoboken-Overpelt S.A., Belgium's major copper-lead-zinc producer, again cut production at midyear to 65% of capacity at its electrolytic zinc plant at Overpelt, east of Antwerp, which has one-third of total domestic capacity. It was feared that additional cuts would be necessary.

Other electrolytic zinc producers were Soc. des Mines et Fonderies de Zinc de la Vieille-Montagne (with about one-half of Belgian capacity at Balen) and Soc. de Prayon S.A. (near Liège).

Iron and Steel.—The steel industry continued to be in trouble throughout Western Europe during the year, but Belgium suffered particularly from outmoded facilities, high costs, overstaffing, and heavy dependence on sluggish export markets. The industry continued to be kept alive by Government financing and guarantees, while company decisions were held in abeyance until the result of new studies became known.

In March, a conference representing Government, steel company, and financial interests established a moratorium suspending investment in new capacity, layoffs, stock transfers, and credit changes. The Government then guaranteed the existing private credit lines, amounting to 30 billion Belgian francs (BF), and granted a further BF10 billion credit to industry members. As a final measure, the U.S. consulting firm McKinsey and Co. was engaged to study the steel industries of Belgium and Luxembourg and to recommend long term measures for improvement.

The individual companies of the steel industry reported heavy losses. The specialty steels producer Forges et Laminoirs de Jemappes was to be liquidated in May but was saved by the Cockerill Group's agreement to set up a successor company, Laminoirs de Jemappes, with BF25 million of Cockerill's capital and BF125 million of Government equity, the first participation ever by the Government in the steel industry. An additional BF100 million would be available as a loan from the Government firm Soc. Nationale de Credit a l'Industrie, and BF140 million would be available as a direct State loan. Jemappes' new strip mill would continue in operation, but the two open-hearth furnaces would be shut down, leaving raw steel capacity at 35,000 tons per year in two 25-ton arc furnaces. Cockerill itself suffered deficits of almost BF4 billion in 1975 and almost BF2 billion in 1976 and expected to lose about BF8 billion in 1977 despite vigorous cost cutting. The Belgian-Luxembourg steel company Métallurgique et Minière de Rodange-Athus S.A. (MMRA) was the object of an emergency salvage operation. (See "Luxembourg.")

The McKinsey report was not released by yearend, but certain details were available. The industry was seen as suffering from outmoded plants, relatively high energy and labor costs, and overreliance on the sale of basic, low-profit products rather than specialty steels, and as only a marginal supplier in export markets. Major cost reductions were needed if the industry was to continue to exist.

In October, the Belgian Minister of Economic Affairs asserted that a large degree of rationalization was imperative in order to save the Walloon (southern and eastern Belgium) steel industry. This included both public and private long term investments, a change of the current product mix (which included only 3% specialty steels compared with 19% in Italy, 17% in the Federal Republic of Germany, and 14% in France), no increase in overall capacity, and large-scale reduction of the work force, which was about 50,000 in 1977.

It appeared almost inevitable that the Belgian Government would be obliged to take a significant equity position in the steel industry, as it did in the Jemappes case, since the debt-equity ratio of many companies was too poor to permit further subsidized credits or credit guarantees. Other Government action would probably be to move workers out of the steel industry into jobs created by new public corporations, as in the MMRA affair discussed later; 20% to 30% of the Walloon steel industry work force (10,000 to 15,000 work-

Digitized by Google

ers) was expected to be affected.

The Belgian steel industry, large both by world standards and on a per capita basis, consisted of the Cockerill Group (S.A. Cockerill-Ougrée-Providence et Espérance-Longdoz) based at Liège, with about one-half of the country's capacity; the Frère Group, consisting of three loosely associated firms (Soc. Métallurgique Hainaut-Sambre S.A., Forges de Thy Marcinelle et Monceau S.A., and Laminoirs du Ruau) around Charleroi; and Maritieme Staalnijverheid N.V. (also called Soc. Sidérurgie Maritime S.A. (Sidmar), near Ghent. Smaller firms included Usines Gustave Boël at La Louvière, Forges de Clabecq S.A. at Clabecq, and MMRA.

Nonmetals.—*Cement.*—Belgian production of all types of cement was nearly 7.8 million tons. The largest of the seven companies in the industry were S.A. Cimenteries Cementbedrijven N.V., producing about 3.1 million tons (of which one-half was at the Lixhe plant near Limburg Province of the Netherlands) and Ciments d'Obourg S.A., producing 2.1 million tons (of which 80% was at the Obourg plant near Mons).

Mineral Fuels.—In February, the Government prepared a draft "White Paper" on energy policy. It discussed the major objectives of the Belgian energy program, including energy conservation, utilization of indigenous sources of energy (particularly coal), encouragement of use of nuclear power for electricity generation, and a general reduction in dependence on imported oil. However, in view of the concurrent dissolution of Parliament and the calling of new elections which led to a new coalition government, the broad lines of a comprehensive energy policy were not clearly defined.

Total primary energy balances for Belgium are given for 1975 and 1976 in table 5.

Coal.—The energy policy statement issued in the national budget that was proposed in September called for a review of the corporate statute of Naamloze Vennootschap Kempensche Steenkohlenmijnen, the coal-mining company operating in the Campine (northeastern Belgium), in order to improve public-sector participation. Also, to settle upon a permanent policy for coal from the Campine, a "massive" study would be undertaken of conventional uses and alternatives, including coal chemistry and gasification. Although the Campine mines were operated by a private company, they received continuing heavy Government subsidies. The energy policy statement also indicated that the policy of closing Walloon mines (those in Wallonia, or French-speaking southern Belgium) would be continued.

Natural Gas.—Natural gas shows were encountered between 4,000 and 4,500 meters in a well drilled by Foraky S.A. for the Ministry of Economic Affairs near the town of Saint-Ghislain, west of Mons. Other indications of the presence of natural gas in pre-Permian strata were found in wells at Focant, southeast of Dinant. The Belgian Administration of Mines planned to undertake an exploration program in 1979 that would include drilling a test hole of 6,000 meters in the Famenne region adjoining the Focant area. Two oil companies, including Petrofina S.A., have asked for concessions in Hainaut and the Campine as a result of the foregoing studies.

A decision was made by the Government to construct a floating terminal for liquefied natural gas at Zeebrugge to receive and store 5 billion cubic meters per year from Algeria; this will be needed to supplement diminishing supplies from the Netherlands in the 1980's.

Petroleum.—The 45-centimeter-diameter, 150-kilometer-long pipeline from Antwerp to Limburg and and Liège was completed early in 1978. The pipeline, with an initial capacity of 2.5 million tons per year of feedstocks such as naphtha, gas oil, and benzenes, would supply areas along the way and finally the DSM chemical works at Geleen, near Maastricht, the Netherlands.

Uranium.—The Commission of the EEC had earlier allocated 5 million units of account (about $6 million) over a period of 3 years for uranium prospecting in the EEC. In 1977, exploration and prospecting projects were financed in five countries, including Belgium.

All future projected Belgian electricity-generating plants were to be nuclear. The three reactors in operation in 1977 (1,650 megawatts-electric) accounted for about 21% of total generating capacity. Two additional plants (1,830 megawatts-electric) were under construction and were to be onstream in 1979 and 1980, and two more (2,000 megawatts-electric) were planned for 1982. All were liquid water reactors. A moratorium on the latter two planned reactors was announced by the Government in July.

LUXEMBOURG

In 1977, many of Luxembourg's industries regained the prerecession production levels, if not the profitability, of a few years earlier, but the dominant steel industry was not among them. Steel tradionally generates almost one-fourth of the GNP.

By the end of the third quarter, steel production by Aciéries Réunies de Burbach-Eich-Dudelange (ARBED), which contributes 90% of the country's steel output, had fallen 8% below even the low level recorded for the same period of 1976. Steel prices continued to decline, and, while ARBED managed to hold down production costs, financing costs rose; losses for the first 6 months were 2.2 billion Luxembourg francs (Lux F),[2] well above the loss of Lux F1.3 billion for all of 1976. The generally bleak outlook for future sales and profitability was attributed by ARBED's board of directors in October to low-priced imported steel flowing into European markets, which reflected ARBED's loss of competitiveness with Japan and the new exporting nations. To meet the threat to the future, ARBED initiated a crisis plan during the year, centered on reducing production costs by the maximum installation of new equipment within the company's means and the swift reduction of personnel. In 1977, some Lux F4.1 billion was invested, in addition to earlier investments in 1970-76 of Lux F18.7 billion, in a massive gamble that the company could survive a few years until the investments paid off.

The second and only other steel producer in Luxembourg, MMRA, a 1-million-ton-per-year producer, was experiencing even greater difficulties than ARBED. In September, the Prime Minister of Belgium announced a joint Belgian-Luxembourg interim settlement of the problem by closing most of the Athus plant on the Belgian side of the border and reducing employment there from 1,650 to 200, reducing the labor force at Rodange in Luxembourg by 700 but not curtailing operations, and providing BF680 million as operating capital until yearend through a debt and tax moratorium, contributions by the owners, and a Belgian Government advance of BF200 million. The McKinsey study currently underway in Belgium was to serve as a basis for solutions to be agreed upon by the Cockerill and ARBED steel companies, the two Governments, and MMRA. The Governments also agreed to compensate the jobless at Rodange through a special Luxembourg-supported anticrisis division of MMRA and to offer a choice to the Athus workers of early retirement, "job cell" employment in other activities, or dismissal with the usual company, EEC, and Belgian Government compensation. The job cell organization would guarantee most wages of surplus employees for about 3 years, aided by a diversification society that would develop new industry in the region. The Rodange-Athus arrangement was seen as a test case of the objectives of the EEC's Davignon Plan for helping the European steel industry. The Davignon Plan called for restricting production and fixing prices while undertaking substantial modernization programs.

[p]Preliminary. [r]Revised. NA Not available.

[1]In addition to the commodities listed, Luxembourg also produces refractory clays and manufactured phosphatic fertilizers other than Thomas slag, but data are not published and information is inadequate to make reliable estimates of output levels.

Subsequently, Cockerill and ARBED, at the instance of the two Governments and the EEC, devised a proposal to rescue MMRA permanently. Principal features of the plan, made public at yearend, included progressive integration of MMRA with ARBED, retirement of the 700 affected workers at Rodange by attrition only, nonreplacement of blast furnaces and cancellation of plans for a new rolling mill, an increase in capital to about Lux F1 billion, and participation in MMRA by official credit and investment societies of the two Governments. Assent of the labor unions involved was to be sought after approval of the proposal by the two Governments, but the unions publicly expressed agreement at the time of the announcement.

ARBED's only underground mine operating during the year, Thillenberg, near Differdange, produced siliceous ore. Steel plants were located at Differdange (specializing in the production of wide-flange beams), Esch-Belval (producing heavy sections and strip), Esch-Schifflange (producing merchant bars, etc.), and Dudelange (producing hot- and cold-rolled flat products).

A new cement plant, with a dry-process kiln of 960,000-ton-per-year capacity, was brought into operation by Intermoselle S.A.R.L. at Rumelange. The plant at Esch-sur-Alzette, operated by S.A. des Ciments Luxembourgeois, was converted to a clinker-grinding plant at the same time. No other cement plants operated in Luxembourg.

The Mineral Industry of Bolivia

By Orlando Martino[1]

In 1977 Bolivia experienced its sixth consecutive year of economic growth, estimated at 4.8%, compared with the 6% to 7% real growth of recent years. The slower growth is attributed chiefly to the decline in agricultural production and the 15% drop in petroleum output. In current dollars the gross domestic product (GDP) grew to the equivalent of $3.6 billion.[2] The rate of inflation was estimated by the Government to have increased to 17% compared with the 12% rate in the 1975-76 period.

The value of output of Bolivia's mining industry accounted for about 6.8% of the GDP. The mining share of gross investment was 8.4%. Benefiting from some increase in production and higher world prices, especially in tin and tungsten, the value of mineral exports grew to $490.5 million, a 30% increase over 1976 exports. However, exports of crude oil declined in value by 40% while natural gas exports increased 22% in value.

The State-owned Corporación Minera de Bolivia (COMIBOL) continued as the largest minerals producer in the country and the largest single tin company in the world. COMIBOL's total mineral sales of $333 million was 30% above 1976 results, reflecting better prices for tin and tungsten, although price declines were incurred for zinc, copper, and bismuth. Despite this improvement, COMIBOL was not able to generate funds to finance adequately its exploration and development programs. COMIBOL's total assets at yearend were valued at $367 million.

In June the Empresa Nacional de Fundiciones (ENAF) completed expansion of its tin smelter at Vinto up to 20,000 tons per year, and by early 1979 was expected to further increase capacity to 30,000 tons with the inauguration of a low-grade tin smelter. In partnership with COMIBOL, ENAF was planning to install a lead-silver smelter-refinery near Potosí.

Yacimientos Petrolíferos Fiscales Bolivianos (YPFB) suffered a 15% decline in crude oil production and a sharp drop in foreign sales. Total sales of $222 million represented a slight increase over those of 1976 but net profit fell 65% to $18.4 million. At midyear YPFB received a credit of $75 million from 34 international banks led by Bank of America to finance construction of petroleum refineries and for exploration and development of its oilfields.

The private mining sector, which has grown steadily since 1952, had a good year because of high tin and tungsten prices. The 31 medium mining companies generated directly or indirectly about $100 million in foreign exchange earnings for Bolivia, and 25% of national mineral output. The medium miners sell over 60% of their tin production to ENAF.

Government Policies and Programs.—In August the Government passed a new law to reduce Bolivia's high dependency on mineral exports by stimulating nontraditional exports—primarily agricultural products—which comprised about 12% of total exports. On April 26, 1977, the Ministries of Mining and Finance issued biministerial Resolution No. 313-77 which extended a 50% reduction on mining export and royalty taxes for additional or "overproduction" for 1977, or until a mining tax reform law is passed. The average of 1972-73 mine production will serve as a basis for determing the amount of overproduction.

A significant advance for the mining industry was achieved with the creation in April 1977 of the National Fund for Miner-

Digitized by Google

als Exploration (Fondo Nacional de Exploracíon Minera). The fund, placed under the Ministry of Mines and Metallurgy, will act as a financing agency to promote the discovery of new mineral resources and the quantification of reserves through detailed mine exploration to be carried out by other Government agencies such as the Bolivian Geological Survey and the Nuclear Energy Commission. The fund was granted $12 million from Federal revenues to be disbursed at $1.2 million yearly for 10 years beginning 1978.

In June the Government issued a new petroleum policy to encourage further exploration by foreign oil companies.

PRODUCTION

Of the four commodities, tin, tungsten, antimony, and bismuth of which Bolivia is a producer and exporter of world significance, only mine production of bismuth increased. However, production of metallic tin and antimony increased 43% and 98%, respectively, because of increased smelter capacity. Among the minerals of lesser importance in world supply, mine production of zinc increased 26% and lead increased 18%. Gold output declined 16%. Output of cement continued to be inadequate to meet domestic demand and production of sulfur continued its sharp downtrend.

COMIBOL's total mineral output, summarized in table 1, came from over 90 mines grouped under 12 mining companies. COMIBOL did not suffer from any miners strikes in 1977. After several years of output at a flat level, COMIBOL's tin production increased 13%. All other minerals showed increases, except for cadmium and tungsten.

The production of hydrocarbons has been of growing importance to Bolivia's economy since 1969. The value of its output represented 3.9% of GDP in 1977 compared with 2.6% of GDP in 1971. Although output of crude oil and natural gas decreased, Bolivia was self-sufficient in both energy resources with a sizeable surplus for export.

In 1977 Bolivia employed 81,100 workers in the mining sector or 3.4% of the total labor force. In 1977 COMIBOL employed 24,750 workers and the medium mining companies employed 7,880.

Table 1.—Bolivia: COMIBOL's total mineral output

(Metric tons of fine content unless otherwise specified)

TRADE

Bolivia's exports of mineral commodities exceeded the high values obtained in 1974. Mineral exports, not including crude oil and natural gas, accounted for 69% of Bolivia's total exports, compared with a 62% share in 1976. With mineral fuels included, the share of total exports increased to 88%. Of the major commodity exports listed in table 4, only the value of exports of antimony and crude petroleum did not increase in 1977. Although the volume of tin exports increased only slightly in 1977, higher world prices, which increased an average of 27%, provided for a 43% increase in tin export earnings. Thus, the dominant role of tin was enhanced from 37% of total exports in 1976 to 46% by 1977. Because of the drop in output of petroleum and natural gas, the relative importance of these fuels in Bolivia's total trade declined from 27% in 1976 to 19% in 1977.

Imports by Bolivia increased 15% in 1977, giving the country a small surplus in its balance of trade. Bolivia's imports of mineral commodities in 1969, the latest official data available, may be found in the Bolivia chapter of volume 3 of the 1972 Minerals Yearbook. The U.S. share of the Bolivian market increased from 25% in 1976 to 33% in 1977 ($214 million).

On June 14, 1977, Bolivia ratified the fifth International Tin Agreement. The new agreement contained a requirement for an economic and price review by Bolivia and for a systematic and periodic review of buffer stock floor and ceiling tin prices. Bolivia sought to establish an antimony producer's group and scheduled a meeting in April 1978.

COMMODITY REVIEW

METALS

Antimony.—Mine output returned to the historical trend following the record high of 1976; nonetheless Bolivia moved to first place as a worldwide producer ahead of the Republic of South Africa. Empresa Minera Unificada S/A (EMUSA) as operator of three antimony mines Chilcobija, Caracota and Espiritu Santo, was Bolivia's largest antimony producer. During 1977 EMUSA produced concentrate with 6,329 tons of antimony content of which 1,950 tons were sold to ENAF and 2,492 tons were exported.

Since its 1976 startup, ENAF's antimony smelter has yet to reach its full capacity of 4,270 tons. ENAF produced 2,322 tons of metallic antimony and 1,411 tons of antimony compounds. Although planning continued on the second 5,600-ton-per-year antimony smelter near Tupiza, the project was delayed because of the weakness in world antimony prices.

Cadmium.—Cadmium has been produced in Bolivia since 1970 as a byproduct of the mining of zinc sulfide ores. COMIBOL's Matilde zinc mine on the east shore of Lake Titicaca was the largest producer with smaller output from New Jersey Zinc Co.'s Huari-Huari operation. About 150 to 300 tons of metallic cadmium was expected to be recovered annually when ENAF's zinc

Digitized by Google

smelter begins operations in 1983.

Copper.—The downtrend in the output of copper of the last four years continued. Copper exports in 1977 declined further by 32% to only 3,174 tons. The largest copper project under development was the sinking of the Centauro shaft in COMIBOL's Corocoro mine with a credit from the Development Corp. of South Africa Ltd.

In January the Japanese firm DOWA Mining Co. Ltd. completed a feasibility study for a copper smelter for ENAF with negative conclusions because of Bolivia's small copper production and reserves. However, COMIBOL planned to initiate leaching and electrowinning operations to treat its oxide ores at Corocoro.

Gold.—Cooperatives working in the Tipuani River (55%), and the South American Placers Inc., (SAPI) dredge on the Kaka River (43%), were the main gold producers in 1977, while COMIBOL accounted for only 2% of output. The Tipuani cooperatives requested the Ministry of Mines and Metallurgy to grant concessions in other areas because the areas being worked were nearing depletion. In May 100% of the shares of SAPI were purchased by the Compañía Minera del Sur (COMSUR), the third largest private medium mining company in Bolivia.

Iron Ore.—All of the limited iron ore exports (4,328 tons) during 1977 from Mutún and Villazón went to Argentina, which buys small amounts of iron ore from Bolivia to diversify its large purchases of ore from Brazil. Kaiser Engineering Co. began the geological evaluation of the Changolla iron deposit, a vein-type orebody with a total iron content higher than that of Mutún, but with smaller reserves. The study was expected to be completed by August 1978.

Iron and Steel.—In September Empresa Siderúrgica Boliviana S.A. (SIDERSA) received the feasibility study of the Mutún iron-steel project completed by Arthur G. McKee and Co. Iron ore, with a 56% iron content would be mined from the delineated Mutún orebody at the rate of 1 million tons per year to feed a 4,000-ton-per-day crushing and screening plant. Limestone would be mined locally at a rate of 305,500 tons per year. Direct reduction of the iron ore was recommended by McKee using 10 million cubic feet per day of natural gas available in the Santa Cruz area. However, blast furnace technology using locally produced charcoal remained under consideration as an alternative. The proposed oxygen steel plant would produce 527,400 tons per year of liquid steel. A rolling mill and continuous casting operation were also proposed by McKee.

During August an agreement was reached with Brazil assuring Bolivia a market for 410,000 tons per year of nonflat steel products, about 10% of the Brazilian market. This revised figure represents an increase of 210,000 tons over the original amount set in 1974, and helps make the Mutún project commercially feasible. The steel sale is subject to Bolivia's export to Brazil of natural gas of 240 million cubic feet per day and the future construction of the gas pipeline from Santa Cruz to Corumbá in Brazil at the border.

Lead.—Lead production increased 18% and future output was expected to respond to higher prices and new projects to come on stream in 1978. The largest lead-silver project is by S.J. Groves which was expected to produce 6,000 tons per year of fine lead by 1980.

Following completion of the feasibility study, ENAF in partnership with COMIBOL was planning to construct the first lead smelter in the Western World operating on the Kivcet process. The lead-silver smelter-refinery, estimated to cost $135 million, is to be located in Karachi Pampa 4 miles from Potosí. Technological aspects of the smelter were being handled by KHD Industrieanlagen AG., Cologne, West Germany. Klockner Industrieanlagen GmbH of Duisburg was in charge of commercial and financial matters, and Sidech PBR and Mechim of Belgium were undertaking the refining section inside the Kivcet smelter. Beginning in January 1981, the new plant was expected to produce 24,000 tons of lead and 6.4 million troy ounces of silver.

Silver.—Exports of silver increased 18% over those of 1976. Although production of silver by small and medium miners decreased slightly, output by COMIBOL was up 10%. A new mill was built by COMIBOL at Vetillas to increase the volume of and recovery from silver concentrates from its rich San Vicente mine in the Department of Potosí. Proved and probable reserves of silver of COMIBOL at yearend were 36.2 million troy ounces plus 22.9 million troy ounces in tailings. Total reserves of the private miners were not available.

Tin.—In 1977 Bolivia was the second major exporter of tin in the world. Exports of metallic tin were 40% of total tin exports

Digitized by Google

of 30,855 tons. Most tin production came from the nationalized mines operated by COMIBOL (71%), followed by medium miners (21%), and the small mining group and cooperatives (8%). COMIBOL's subsidiary companies of Catavi, Huanuni, Unificada, Quechisla, and Colquiri were the main tin producers among 12 mining companies. Although COMIBOL's mine costs decreased slightly by 2%, overall costs including taxes increased to $4.38 per pound, compared with $3.80 in 1976. World tin prices began the year at over $4.00 per pound and continued rising up to $5.70 per pound by December.[3] Bolivia's tin exports in 1977 increased by less than 2%, but export value increased sharply by 43%, thus contributing 46% of the country's total commodity exports. Western Europe and Japan took 41% of Bolivia's tin exports; the United States, 41%, Latin America 8%, and the centrally planned economy countries, 10%.

COMIBOL continued its program to improve its 50% tin recovery rate. To help overcome this problem, COMIBOL was expected to begin concentration by volatilization in a Soviet-built plant by the revised date of September 1979. Bolivia signed a new contract with Machinoexport of the U.S.S.R. for a second volatilization plant at Machacamarca, 25 kilometers south of Oruro. COMIBOL signed a contract to recover colloidal tin and zinc in a joint venture with Englehardt Mineral Co. COMIBOL's stock of tin at yearend was estimated at 771 tons.

Bolivia continued to increase the amount of tin smelted in the country. ENAF purchased 14,539 tons of tin concentrate, compared with 10,108 tons in 1976. During 1977, ENAF produced 12,788 tons of metallic tin and exported 12,095 tons. The increase in ENAF's tin production above the 9,185 tons in 1976 was due to the increase in its Vinto smelter capacity from 11,500 tons to 20,000 tons when the expanded plant was inaugurated in June 1977. Further expansion up to 30,000 tons was scheduled for January 1979 with the inauguration of the 10,000-ton-per-year, low-grade tin smelter at Vinto. Among the private smelters, Fundicion de Estaño Oruro S.A. (Fundestaño) produced 439 tons of tin (exporting 200 tons) and Bera de Bolivia S.A. exported 3 tons and 224 tons of tin-lead alloys. Fundestaño added a new 50-ton-per-day cyclone furnace and was expanding the capacity of its electrolytic refinery to 3,500 tons of tin in 1979.

On December 27, 1977, ENAF signed a contract with RAZNOIMPORT of the USSR to supply 4,500 tons of metallic tin during 1978. The sales contract was valued at $50 million and represented 25% of ENAF's production. The U.S.S.R. began buying Bolivian tin in 1970, and as of 1976 had purchased a total of 9,553 tons.

The medium miners sold 65% of their tin production (concentrate) to ENAF.

Digitized by Google

Tungsten.—Tungsten is one of the four minerals in which Bolivia is a producer of world significance. Following Canada in importance, Bolivia supplied 23% of U.S. imports of concentrate in 1977.

Despite record high price levels in 1977, tungsten exports decreased 15% to 2,800 tons. Output by COMIBOL and small miners declined while that of medium miners increased from 1,557 tons in 1976 to 1,602 tons in 1977, contributing 53% of the country's total. International Mining Co. (IMCO), Bolivia's largest tungsten producer, continued development programs in its Chojlla, Enramada, and Chambillaya mines designed to increase output to 2,200 tons of tungsten per year in 1978. ENAF formed a joint venture with IMCO to produce 2,000 tons of ammonium paratungstate per year. ENAF was expected to issue a construction contract for a ferrotungsten plant in August 1978 to supply the Andean Common Market.

Uranium.—Bolivia has not been a producer or exporter of uranium. In November a pilot plant built by Argentina was inaugurated to process the uranium ore of the Cotaje deposit owned by the Comisión Boliviana de Energía Nuclear (COBOEN). The plant has two leaching cells capable of producing a 66% U_3O_8 concentrate. The number of cells will be increased to six in 1979. Production in 1978 was projected at 1 metric ton of yellow cake. Reserves at Cotaje were estimated at 66,000 tons of ore grading 580 grams of U_3O_8 per ton.

After 3 years of exploration by the Italian firm, S.p.A., results have been disappointing and it appeared its program would be terminated in 1978. COBOEN carried out its own exploration programs and in 1977 made some discoveries in Potosí. COBOEN completed the first stage in 1977 of civil works for a nuclear research center in Viacha near La Paz. A reactor was expected to be installed by 1980.

Zinc.—Mine output of zinc increased 26% but fell short of the 80,000 tons projected for 1977 on the basis of programs by COMIBOL and New Jersey Zinc at its Huari-Huari mine. Questions were raised over the prospect that Bolivia would be able to supply the necessary concentrates for the 100,000-ton-per-year zinc refinery planned for 1983. COMIBOL accounted for 57% of total zinc output, medium miners accounted for 42%, and small mines the remainder. Zinc output by the medium miners increased by 137% in 1977.

ENAF proceeded with its plans to install a zinc refinery in the Department of Potosí. Klockner Industries Anlagen of West Germany was still preparing a feasibility study of the associated zinc smelter and sulfuric acid plant.

NONMETALS

Historically, nonmetallic minerals have been of minor importance in the mineral industries of Bolivia. In this group only exports of sulfur have been of relative significance. Nonmetallic exports have represented less than 0.1 of 1% of total mineral exports.

Barite.—Construction of the barite and bentonite benefication plant at Oruro was completed during the year by the Baroid Div. of NL Industries Inc. in a joint venture with Mosamar of Bolivia, and initial output was expected in early 1978.

Cement.—Cement consumption increased 22% in 1977. Bolivia continued to import some cement; however , projects were being planned to increase cement production significantly in the near future. Limestone and cement production were estimated at 500,000 tons and 267,000 tons, respectively, in 1977.

In 1977, the Inter-American Development Bank approved two loans totaling $48 million (one from the Venezuelan Trust Fund) to help finance Bolivia's fourth cement plant, which will expand the country's cement capacity from 260,000 tons per year to 670,000 tons per year. The plant will be built at Yacuses about 75 miles west of Corumbá on the Brazilian border. Eventual export of cement to Brazil was contemplated.

Fertilizer Materials.—YPFB was planning a joint venture with Brazil for a $200 million fertilizer complex in Puerto Suarez, 500 kilometers east of Santa Cruz. Plans are to build a 1,000-ton-per-day ammonia plant from which a 1,600-ton-per-day urea plant will be fed. The feasibility study was being performed by Japan Consulting Institute and the first draft was received by YPFB in early February. The project is dependent upon the outcome of the negotiations between Bolivia and Brazil regarding the gas pipeline to be built between Santa Cruz and Corumbá.

Salt.—In Bolivia salt is mined primarily at the Salar de Uyuni by mining cooperatives for about $2.50 per ton. Plans have been completed to build an iodized salt plant in Oruro situated 250 kilometers

Digitized by Google

north of the Salar, as well as a plant to produce caustic soda (sodium hydroxide).

Sulfur.—The sharp downtrend begun in 1974 continued. Output declined 58% to 6,276 tons, compared with 56,393 tons in 1973. All sulfur production came from mines in the western cordillera of Bolivia.

MINERAL FUELS

Natural Gas.—Production of natural gas decreased 3.2%. There were 250 producing wells in 12 gasfields of which Rio Grande, the largest field had a 2% increase. The greatest declines in output were at Caigua field, 42%; and Guairuy field, 68%. Exports to Argentina, the principal market, increased 4.3% over those of 1976 to 57,887 million cubic feet at a value of $66.8 million (a 22% increase). Negotiations continued on the proposed exports of natural gas to Brazil. Exports of natural gas represented 9.4% of Bolivia's total exports.

In January 1977, Bolivia and Argentina agreed to increase the price of dry gas in five quarterly increments from $0.93 per thousand cubic feet to $1.20 per thousand cubic feet in April 1978. These prices apply to dry natural gas without considering premiums for condensates and natural gasoline. Natural gas sales equaled petroleum export sales in 1977 and were expected to surpass the value of petroleum exports in 1978.

Domestic sales of natural gas increased 16% to 7,288 million cubic feet, but represented only 5% of total gas output. Future domestic consumption of natural gas would rise sharply if the proposed petrochemical complex and the Mutún iron-steel complex are implemented.

Occidental Boliviana Inc., continued to delineate its Tita discovery in the Chaco Basin southeast of Santa Cruz. Twelve of the 13 Tita field wells drilled by yearend contained gas and liquid hydrocarbons. Proven Tita reserves at the end of 1977 have been estimated by consultants DeGolyer and McNaughton at the revised figure of 344 billion cubic feet of gas and 17.2 million barrels of oil and condensate. The Tita discovery proved to be one of the largest gasfields in Bolivia. Production was scheduled to begin in early 1978. An 85-kilometer gas pipeline was under construction by Williams Bolivia S.A. to connect Occidental's gas output with the main Bolivian export line to Argentina by mid-1978. YPFB also completed construction of a crude oil pipeline connecting the Tita field with the oil export pipeline system to the terminal in Arica, Chile. Bolivia has 13 oil and gas pipelines, totaling 3,380 kilometers in length.

Under the production-sharing contract with YPFB, Occidental is entitled to 50% of the oil produced and its part of the gas produced on a sliding scale from 50% to 47% depending on the volume. In October Occidental signed a second production-sharing contract with YPFB covering an additional 1.5 million acres in the southern part of the Chaco Basin.

At yearend total proved Bolivian reserves of natural gas were estimated at 5.7 trillion cubic feet, a 21% increase over the 1976 estimate.

In August, a team from the Japan Natural Gas Association (JNGA) visited Bolivia to develop a program on efficient uses for Bolivia's natural gas resources.

Table 7.—Bolivia: Distribution of natural gas production

(Million cubic feet)

	1975	1976	1977	Percent of total, 1977	Percent change
Injected	60,615	71,442	70,537	47	-1.3

Petroleum.—Results were disappointing in 1977. Production of crude oil, which has been in a downtrend since the peak year of 1973, decreased 15% and exports, mostly to Argentina, dropped by 44% to 4.49 million barrels. Oil revenues declined from $113 million in 1976 to $67 million in 1977. The average price for Bolivia's sulfur-free light oil was $13.95 per barrel in 1977. Domestic consumption, which increased by 17% in 1977, reduced further Bolivia's ability to export oil with declining production. There was no price increase for domestic gasoline or other refined products. Output from selected oilfields is shown in table 8. Only three old oilfields increased production. The Espejos and Montecristo fields began production in 1977.

In 1977, drilling decreased 30% over that of 1976 to a total of 34,800 meters, 60% of which was drilled by the State oil company, YPFB. In Southeastern Bolivia, Occidental made an oil discovery in the Techi structure southeast of Tita. A second discovery was made by the group Tesoro Bolivia Petroleum Co., Canadian Superior Oil Ltd., and Zapata Exploration Co. in La Vertiente structure in Southern Bolivia 15 kilometers southeast of Villamontes in the Department of Tarija. Tentative estimates give 200 million barrels of crude oil and 3.5 trillion cubic feet of gas. YPFB discovered a gasfield in the Nupucu structure east of La Vertiente. Southern Bolivia was the second richest oil-gas region after Central Southern Bolivia, the site of most of YPFB activities. Texaco Bolivia Inc., and Getty Oil Co., were the only foreign operators in Northwestern Bolivia, but by April 1977 they had no success and the contract with YPFB was dropped.

During 1977, two new operations contracts were signed by YPFB: one with Occidental covering areas in the departments of Santa Cruz, Tarija, and Chuquisaca and the other with Tesoro for the Tarija area. As of December 1977, Bolivia had signed a total of 19 operations contracts since the General Hydrocarbons Law of 1972. However, at yearend only three foreign groups were active: Occidental, Tesoro, and Phillips Petroleum Co. (Bolivia).

On June 8, 1977, the Government issued a new hydrocarbons policy to encourage further exploration by foreign companies. The new policy provided for: (1) better production sharing for contractors, (2) the possibility of special services contracts to develop production with secondary recovery methods, (3) encouragement of greater use of gas products, and (4) the opening of YPFB reserve areas to exploration by contractors.

At yearend Bolivia's proven petroleum reserves were estimated at 181 million barrels. This figure includes estimates of reserves at Tita and Techi. From geological data this estimate might be increased to over 400 million barrels but stratigraphical problems in fields like Montecristo and Tita make part of the petroleum unrecoverable. La Vertiente requires further drilling to verify early estimates.

Petrochemicals.—The Bolivian petrochemical industry is an emerging industry, helped along by the product assignments of Decision 91 of the Junta de Cartagena of the Andean Common Market (ANCOM) plus the availability of locally produced hydrocarbon feedstock. There are also several projects unrelated to ANCOM that are for the domestic market only or bilateral in nature. The cost of projects to be undertaken during the current fiscal year plan, 1976-80, are estimated at over $400 million. The Stanford Research Institute completed in early 1977 an optimization study for a part of the planned Bolivian petrochemical industry and presented several options to YPFB for proceeding with its investment. No basic petrochemical industry exists in Bolivia, but the plastic industry imports basic raw materials to manufacture finished products. The plastics industry has been an important growth industry over the past several years and the trend should continue.

The Mineral Industry of Botswana

By Janice L. W. Jolly[1]

The importance of mineral production to Botswana's economy has increased significantly during the 11 years since independence. Development of mineral resources has been a major factor in the nation's steady positive growth. During the 1978-85 period, minerals were expected to continue to make a major contribution to the economy, sustaining a growth rate in the gross domestic product (GDP) of at least 10% per year.[2] Total mineral production was valued at $144 million[3] in 1977, contributing 28% of the 1977 GDP of about $506 million at current prices.

Previously committed mineral projects were to ensure further growth of the mineral sector. Among these were expansion of the Orapa and Letlhakane diamond mines, opening of a new diamond mine by 1982, and expansion of nickel-copper production capacity. The Government's policy was to allow the private sector to continue to be the primary mechanism for achieving these goals, providing technical and management expertise, marketing channels, and most of the financing for mineral development. The Government would negotiate long-term agreements (up to 25 years) for development, operation, and management of the mines.

The principal policies for guiding mineral development were: The Mines and Minerals Act (Act 30, 1976) which describes the requirements and rights of investors, a negotiated fiscal arrangement suiting the mineral deposit characteristics, direct Government equity participation (normally 15% to 25%) and equivalent board representation, and Government participation (financial and policy) in the provision and operation of infrastructure. In granting mineral exploration licenses, preference was to be given to companies that would explore less developed areas. The Okavango Swamps and Chobe National Park, where ecological systems might be disrupted by mining development, were exempted from exploration efforts. The Government was to escalate regional exploration of the Kalahari Desert, which covers 80% of the country. A recent aeromagnetic survey was made of this area. Exploration was also taking place for asbestos, chromite, and uranium. Small deposits of copper, copper-nickel, and gold that were located by recent investigations were being evaluated.

Results of the completed airborne reconnaissance survey that covered 80% of Botswana were released on October 17 and made available through the Botswana Geological Survey Department (Lobatsi) and the Canadian International Development Agency (CIDA) (Ottawa, Canada). The survey was undertaken by the Geological Survey in association with CIDA. Several large magnetic anomalies were revealed by the exercise.[4]

Botswana's ties with the Republic of South Africa and Southern Rhodesia remained of crucial importance. Botswana relied on the Republic of South Africa for 90% of its imports, for an export route to the sea, and for the substantial revenues derived from its membership in the South African Customs Union. Botswana's share of Customs Union revenues amounted to about $44 million in fiscal 1977-78. In addition, 43,000 workers, about half of the nation's formal labor force (or wage sector), were working in the Republic of South Africa, mostly in the mines. Botswana's

Digitized by Google

mines employed 4,500 people, representing 5% of the wage sector employment. The wage sector was 9% of the entire population in 1977.

PRODUCTION AND TRADE

In 1977, Botswana's mineral production consisted of copper-nickel matte, valued at $82.8 million;[5] diamond, valued at $58.6 million; coal, valued at $2.6 million; talc, valued at $41,045; and semiprecious stones, valued at $19,300.[6] The Selebi-Pikwe mine reached full production during the last half of 1977 but continued to face the problem of depressed world market prices for copper and nickel. Diamond prices, on the other hand, were experiencing the effects of renewed demand.

Botswana's diamond output for the first half of 1977 was up 37% over that of the comparable 1976 period. This increase was partly owing to the production of a second mine at Letlhakane which started in late 1976 at an annual rate of 320,000 carats per year. Exports of diamond from the Orapa mine were valued at $38.6 million for the first half of 1977, compared with $27.4 million for the comparable 1976 period. A total of 2.7 million carats was produced in 1977 compared with 2.4 million carats in 1976.

In 1976, Botswana's copper-nickel matte was excluded from the benefits of the 1974 U.S. trade act and Generalized Selected Preference (GSP) eligibility, which would have exempted it from tariffs. Imports into the United States during the first 10 months of calendar year 1977 were valued at $12 million and accounted for 75.6% of total U.S. imports of copper matte. Therefore, Botswana's matte was again excluded from GSP eligibility and was subject to the tariff for the period March 1, 1978, to March 1, 1979, under the competitive need provisions of the act. All of the copper-nickel matte produced at the Selebi-Pikwe mine is shipped to AMAX Inc.'s Port Nickel, La., refinery for processing into metal.

Late in 1977, AMAX wrote off its entire carrying value ($91.7 million) in Botswana RST Ltd., and the debt and marketing arrangements between other investment partners were renegotiated and concluded on March 16, 1978. In 1977, a new sales agreement negotiated between Bamangwato Concessions Ltd. (BCL) and AMAX replaced a previous agreement with Metallgesellschaft A.G. (Federal Republic of Germany). Under the new agreement, all of BCL's product is sold as matte to AMAX. AMAX has undertaken BCL's obligations to sell nickel and copper in the Federal Republic of Germany.

Botswana imported about 700,000 barrels of petroleum products from refineries at Durban in the Republic of South Africa during 1977. During the first quarter of 1977, about 6,500 tons of coal was imported and 86,750 tons of coal valued at $526,446 was produced. Coal imports in 1976 totaled 28,540 tons valued at $269,000.

Table 1.—Botswana: Production of mineral commodities

(Metric tons unless otherwise specified)

COMMODITY REVIEW

METALS

Copper-Nickel-Cobalt.— During 1977, most of the technical problems at BCL's Selebi-Pikwe mine were apparently solved. BCL is owned 85% by Botswana RST and 15% by the Botswana Government. The recovery of metals from the ore was dramatically improved, increasing from roughly 50% in 1975 to 60% in 1976 and to about 70% in 1977, but there was still substantial room for improvement. A changeover from oil to coal in certain parts of the production process was considered a useful step. Performance in the first 6 months of 1977 was affected by the poor condition of the flash smelter in January and February and normal smelter shutdown in March and April. A major overhaul of the flash furnace was carried out during the shutdown period, and production in the last 6 months set a record high of 19,300 tons, compared with the previous record of 17,300 tons for the second half of 1976. Production of copper-nickel-cobalt matte for 1977 was 30,800 tons compared with 32,500 tons in 1976. Ore milled during 1977 totaled 1.9 million tons, containing 1.02% nickel and 0.83% copper.[7]

Probably the most serious factor affecting the financial performance of BCL in 1977 was the decline in the price of nickel and copper during the year. A serious overproduction of both metals continued to aggravate the problem of large inventories already affecting the world market. As a result, BCL continued to be unable to repay its indebtedness. By December 31, 1977, $151 million in loans had been advanced to BCL, on which about $44 million in interest had accrued. BCL had a net loss of about $46 million in 1977.

The need for major shareholders to invest in BCL was straining cash-starved Zambia Copper Investments Ltd. (ZCI), which had an 11.75% interest in Botswana RST and which was also experiencing the negative effects of the sagging copper market. AMAX took steps to completely write off the carrying value of $91.7 million it had invested in Botswana RST, which was the entire value of AMAX's 29.8% equity in Botswana RST. AMAX had plans to continue making significant cash advances to Botswana RST as the case warranted. Botswana RST's outstanding loans from Kreditanstalt für Wiederaufbau (KFW) and Industrial Development Corp. of South Africa Ltd. were reduced by prepayments without premium. Prepayment of the KFW loan reduced the effects of appreciation of the Deutsche mark. A claim by Triomf Fertilizer (Proprietary) Ltd. against BCL for nondelivery of sulfur by a subsidiary and for cancellation of the contract was settled in 1977 for $3.9 million.

Under a revised agreement, a 3% royalty on the gross value of matte sold by BCL was payable to the Government effective January 1, 1977, on a semiannual basis. This change effectively represented a substantial increase from previous royalty arrangements that provided for a royalty based on profits, subject to a minimum of $905,600 per year. After protracted negotiations between the Botswana Government, the major lenders to BCL, and BCL's principal shareholders, agreements were expected to be announced in 1978 for restructuring of sales and financing arrangements.

NONMETALS

Diamond.—De Beers Consolidated Mines Ltd. and the Government of Botswana agreed to jointly develop the large diamond pipe discovered in 1973 by De Beers at Jwaneng in the southern part of the country. Following the 1975 agreement giving the Botswana Government a 50% interest in De Beers Botswana Mining Co. (Pty.) Ltd. (Debswana), the Government was expected to take up an option to subscribe for a further 20% of Debswana's equity. The Government's equity was to be increased by sharing in the cost of bringing the new Jwaneng mine into production.

Development of the mine and infrastructure was expected to take about 4 years. It was expected to cost about $250 million to bring Jwaneng into production; 10% of the costs was to be financed by export credits, leaving about $45 million for the Government to finance. A loan was to be financed through the First National Bank of Boston and an international consortium of banks, with an average interest rate 2% higher than the London Interbank Offer Rate (LIBOR) on three tranches of $15 million each.

Development of Jwaneng was to include construction of a paved road from Kanye to Jwaneng, a power station, and water and housing provisions for about 2,000 people. The Jwaneng diamond pipe was buried by about 30 to 50 meters of Kalahari sedi-

Digitized by Google

ments. Apparently, enough water was located to supply needs during the construction period, but permanent supplies for the mine and township may ultimately have to be piped from near Gaborone. Commercial production was scheduled for 1982 at an initial annual rate of 3.5 million carats, increasing to 6 million carats. Orapa and Letlhakane, also operated by Debswana, are expected to produce approximately 4.8 million carats each under an expansion program to be completed in 1978.

Production from Jwaneng will be sorted in Gaborone by a subsidiary of Debswana, Botswana Diamond Valuing Co. Ltd., and marketed through the Central Selling Organization (CSO). Management of the mine is to be based in Gaborone, with De Beers and Anglo American Corp. Botswana Ltd. responsible for technical services.

The capacity of the Orapa mine was being increased from 2.3 million carats to 4.5 million carats per year by the end of 1978. The Letlhakane mine, which started production in 1976, had worked up to its design capacity of 320,000 carats in 1977 and was also under expansion.

Soda Ash and Salt.—A Japanese economic mission visited Botswana in October to investigate possible cooperation in mining. A Japanese company was reportedly interested in evaluating the Sua Pan salt and soda ash resources, with the possibility of exploitation by 1980.

MINERAL FUELS

Coal.—Botswana was making an effort to become more self-sufficient in coal. Coal production in the first half of 1977 was up 84% over that of the same period of 1976; even so, about 38% of the 1977 coal production occurred in the last quarter. The Morupule colliery produced a total of 294,039 tons in 1977, valued at $2.6 million. The colliery supplies both the Selebi-Pikwe complex and Botswana Power Corp.

Botswana's large coal resources were estimated at about 40 billion tons. As a result of the energy crisis beginning in late 1973, increased interest in Botswana's coal spurred renewed exploration. The initial results confirmed that the coal is of steam coal quality and that it can be washed to produce a low-sulfur, export-quality steam coal product. The lack of adequate transport systems was the major constraint on development of an export market.

Petroleum.—A project to increase Botswana's oil reserve storage capacity to a 3-month supply was underway and would be completed by 1979. The project was expected to cost $4.2 million. The Federal Republic of Germany was to assist in the construction of two depots.

The Mineral Industry of Brazil

By Orlando Martino[1]

In real terms, Brazil's gross domestic product (GDP) grew 4.7% in 1977 to $164 billion[2] compared with the 9.2% growth in 1976. The rate of inflation continued high at 39%, a decrease from the 46% rate of 1976.

Although the mineral sector represented less than 2% of the GDP, it accounted for 11% of Brazil's total exports. Production of some 60 minerals and mineral fuels in 1977 was valued at $2.9 billion, a 10% increase at constant prices compared with that of 1976. In the period 1975-77, the value in real terms of mineral output increased at an average annual rate of 12%. The total of $2.9 billion includes mining output and the extraction of coal and petroleum but does not include the value added in the production of refined metals and semimanufactures such as crude steel, ferroalloys, and fertilizer materials. The relative importance of the various mineral groups is shown in the following tabulation:

	Percent of total		Percent change in group value in 1977
	1976[r]	1977	
Metals	35.7	30.1	-8
Nonmetals	30.9	36.5	+30
Mineral fuels	32.4	32.6	+11
Diamond and gem stones	1.0	.8	-12

[r]Revised.

Of the total value of mineral output of $2.9 billion, 10 commodities accounted for 84.5%, as follows: Petroleum (28.3%), iron ore (20.2%), crushed stone (13.8%), limestone (9.2%), coal (2.7%), marine salt (2.6%), pyrochlore (2.2%), manganese (2.0%), tin (1.9%), and natural gas (1.6%).

It was estimated that 76% of Brazil's nonfuel mineral production was in the hands of the Government, some 16% was owned by multinational companies, and about 8% was controlled by private Brazilian investors.

Construction of the Serra dos Carajás iron ore project, designed by the Cia. Vale do Rio Doce (CVRD) to mine up to 50 million tons per year of high-grade iron ore, was stalled during 1977 because of continued weak demand of the world steel industry. Construction work proceeded on the large Trombetas bauxite project in the Amazon basin, with initial output scheduled for 1979.

Planning continued on several aluminum smelter projects under Brazil's ambitious nonferrous development plan, and a resolution about the future of the Tubarão steel plant was expected by early 1978. SAMARCO Mineração S/A's iron ore mining-slurry pipeline-pelletizing operation was initiated in 1977 in Brazil's "Iron Quadrangle."

The State-owned oil company, Petróleo Brasileiro S/A (PETROBRAS) announced the start of a massive, 4-year Strategic Oil Exploration Program designed to establish the extent of Brazil's reserves. Intensified exploration by PETROBRAS resulted in a 27% increase in proven oil reserves by yearend. PETROBRAS signed several risk contracts with foreign oil companies for exploration. During 1977, the National Alcohol Program for gasahol expanded, and experimentation continued at the São Mateus do Sul oil shale recovery plant. PETROBRAS created a new subsidiary company, PETROMIN, to engage in mineral production and marketing, particularly of the large potassium reserves in Sergipe.

Digitized by Google

Government Policies and Programs.—The Government pursued a policy of restricted growth and continued to stress two priorities in 1977—reduction of the inflation rate, partly through restraint on investments by companies in the public sector, and improvement in Brazil's international trade situation by expansion of exports and restraint of imports. However, major projects in priority sectors such as minerals and energy development moved actively ahead. Some progress was made in Brazil's nonferrous metals plan, and work started on phase 3 of the steel expansion program. Construction of the cracking unit at the third petrochemical complex in Rio Grande do Sul was begun.

During 1977, the Government decreed a number of modifications of its import restrictions. In June, the prior import deposit was waived on imports of machinery and equipment by Government agencies and State enterprises. In July, petroleum equipment need for development of the Campos basin was exempted for 2 years from the requirement that State enterprises buy Brazilian equipment when available ("Law of Similars"). In September, the requirement of a deposit from importers prior to initiating imports was waived for a number of commodities including copper, lead, zinc, and aluminum scrap. These modifications were not viewed as a significant departure from the Government's import substitution policy but were intended to expedite projects and to be anti-inflationary.

In March, the Government refined its foreign investment policy. The policy, contained in a resolution of the Council for Economic Development, was designed to obtain greater control in selecting foreign investment while seeking to avoid monopoly situations and investment by an excessive number of producers in any given commodity. Investments by foreigners in Brazil's mineral extractive industries played a minor role compared with investments by Brazilian state and private entities. Foreign investment in the mineral extractive industries of Brazil represented only 2.3% or $258 million of the total foreign capital registered by the yearend.

During 1977, additional domestic and foreign investments in Brazil's mineral extractive industries increased 86% to $265 million, allocated as follows: Beneficiation facilities, 67%; mine development, 26%; geological exploration, 4%; and other, 3%. New investment in iron ore production dominated at 40%, followed by phosphates (31%), copper (11%), and other (18%).

As a consequence of exploration efforts by the Government and private entities, the Departamento Nacional da Produção Mineral (DNPM) of the Ministry of Mines and Energy reported substantial increases in the measured reserves of several minerals including silver, lithium, copper, bauxite, graphite, phosphate, kaolin, and petroleum. The geological prospecting subsidiary of CVRD, Rio Doce Geologia e Mineração (DOCEGEO), made promising discoveries of gold and cassiterite at Andorinhas and São Félix do Xingú in the State of Pará. Prospecting by DOCEGEO under the Camaquã project increased copper reserves from 12.7 million tons to 25.5 million tons of copper grading 1.14%.

Two changes were made in the Brazilian mining code administered by DNPM. The first change required payment for a mining claim at the time it is logged. The second provided for decentralization of the licensing procedure for construction materials including sand and gravel. The mapping program started by DNPM in 1971, Radar na Amazonia (RADAM), to assist in evaluating the mineral and economic potential of the Amazon basin was extended to cover the rest of Brazil, and the program was redesignated RADAMBRASIL. DNPM published its detailed program for 1977 covering its activities in mineral economics, control of mining concessions, metallurgical research, basic mapping and exploration, and evaluation of mineral resources.

The Brazilian Government exploration company, Cia. de Pesquisas de Recursos Minerais (CPRM), carried out a diversified program of mineral exploration and geophysical and geochemical studies. From 1970 when operations began until the end of 1977, CPRM drilled a total of 1 million meters. Drilling operations in 1977 focused on the search for uranium, coal, and copper, mostly for the account of Empresas Nucleares Brasileiras S/A (NUCLEBRÁS) and DNPM. CPRM was constructing the Center for Mineral Technology (CETEM) on the campus of the University of Rio de Janeiro that was scheduled to begin operations in mid-1978.

Exploration was also carried out by mineral companies organized and owned by the States of Bahia, Goiás, Mato Grosso, Minas Gerais, Rio de Janeiro, and Rio Grande do Sul.

Digitized by Google

PRODUCTION

Following the 1976 pattern, nonmetallic mineral products in 1977 experienced the greatest growth in value, followed by mineral fuels. The metals sector output declined in real value. As a consequence of the continued weak demand in the world iron and steel industry, output of iron ore and manganese ore decreased 13% and 11%, respectively. However, Brazil maintained its rank as the third largest world producer of iron ore after the U.S.S.R. and Australia. The strong upward trend in the production of crude steel continued, with an impressive increase of 22%, and total output of ferroalloys increased 21% to a record high. Ferromanganese output increased 31%.

Brazil continued to make progress in its ambitious nonferrous metals development program but remained dependent on foreign sources for nonferrous metals except tin. For copper, nickel, and zinc metals, demand in 1977 increased at a higher rate than domestic production. The following tabulation below gives the percent changes in 1977 in output and demand compared with 1976 levels.

	Output		Metal demand
	Ore	Metal[1]	
Aluminum	+35	+20	+19
Copper	--	--	+21
Lead	-6	+11	--
Nickel[2]	-20	+18	+23
Tin	+17	+16	+3
Zinc	+61	+9	+12

[1]Primary metal including refined metal from imported concentrate.
[2]In terms of ferronickel.

Among the precious metals, gold output increased 9% and silver output increased more than 15 fold. Monazite concentrate output was up 52%. Production of tungsten concentrate increased 20%, and zirconium increased 52%, both achieving record high production levels.

Continuing its steady growth trend, output of portland cement increased 10%. Notable increases in production of nonmetals included barite 52%, kaolin 24%, graphite 53%, crude quartz 31%, slate 250%, and sulfur 49%. Output of vermiculite increased a dramatic 622%.

Among the fertilizer materials, production of crude phosphate was up 5%, manufactured phosphate 25%, manufactured and nitrogenous fertilizers 26%.

Substantial production declines occurred in bentonite (24%) and crude mica (65%). Of the mineral fuels, gross natural gas output increased 10%, but crude petroleum decreased 7%, continuing a downward trend. Output of metallurgical and steam coal achieved historic highs, increasing 24% and 26%, respectively.

In 1977, total employment in the mineral industry was 65,000 workers, distributed as follows: Iron ore 19%, coal 15%, limestone 12%, mineral water 7%, gold 6%, manganese ore 4%, and tungsten 3%. Mining was most active in the State of Minas Gerais, which accounted for 39% of miners, followed by Santa Catarina with 13%.

Table 1.—Brazil: Production of mineral commodities[1]

(Metric tons unless otherwise specified)

Commodity	1975	1976	1977[p]
METALS			
Aluminum:			
Bauxite, dry basis gross weight	802,294	826,715	1,119,510
Alumina	267,500	303,000	372,000

Table 1.—Brazil: Production of mineral commodities[1] —Continued

(Metric tons unless otherwise specified)

Commodity		1975	1976	1977[p]
MINERAL FUELS AND RELATED MATERIALS —Continued				
Petroleum —Continued				
Refinery products:				
Gasoline	thousand 42-gallon barrels	88,903	90,013	82,692
Jet fuel	do.	10,636	11,152	11,252
Kerosine	do.	3,988	4,264	4,522
Distillate fuel oil	do.	77,229	87,737	96,624
Residual fuel oil	do.	95,759	98,725	101,800
Lubricants	do.	1,497	2,252	2,378
Other	do.	41,112	44,546	48,898
Refinery fuel and losses	do.	11,140	9,705	9,774
Total	do.	330,264	348,394	357,940

[e]Estimate. [p]Preliminary. [r]Revised.

[1]In addition to the commodities listed, molybdenite and bismuth are also produced, but output is not reported and available information is inadequate to make reliable estimates of output levels.

[2]Exports.

[3]Smelter and/or refined metal.

[4]Includes baddeleyite-caldasite.

[5]Less than 1/2 unit.

[6]This material apparently includes crude quartz used to produce quartz crystal (listed separately in this table) as well as additional unreported quantities of common quartz.

[7]Produced from a portion of the crude quartzite listed; the quantity of crude quartzite processed was as follows: 1975—78,178 tons; 1976—61,542 tons.

TRADE

In 1977, Brazil eliminated its trade deficit that developed during the world energy crisis of 1974. Trade balance was achieved by a 20% increase in total exports to $12.14 billion and a 3% decrease in imports to $12.0 billion.

The mineral trade deficit, however, increased 10% to $4.94 billion, reflecting Brazil's increasing dependence on foreign sources for its nonferrous metals, fertilizer materials, coal, petroleum, and natural gas. Mineral exports decreased 3% from the revised 1976 value of $1.48 billion to $1.44 billion, while mineral imports increased 7% over the revised 1976 value of $5.97 billion to $6.38 billion. Mineral exports, mostly iron ore, manganese, and tungsten, represented 12% of Brazil's total exports; mineral imports, chiefly petroleum, made up 53% of total imports.

The following tabulations show, in percent, the relative importance of the leading mineral ores and fuels in Brazil's international trade. Primary metals and mineral compounds such as fertilizer materials are not included.

Exports	1975	1976	1977
Metals	88.8	93.9	95.4
Iron	80.0	86.0	88.9
Manganese	7.0	5.7	3.1
Tungsten	.8	.6	1.5
Columbium	.7	1.1	1.0
Other	.3	0.5	.9
Nonmetals	1.7	1.0	1.8
Gems and diamonds	2.2	1.9	1.8
Crude	.9	.9	.8
Polished	1.3	1.0	1.0
Mineral fuels	7.3	3.2	1.0
Petroleum	6.5	3.1	.7
Others	.8	.1	.3

Among primary mineral commodities, exports declined for the metallic ore group (11%), diamonds and gemstones (16%), and energy products (73%). In contrast, the value of exports of nonmetallic ores increased by 56% common metals and related semimanufactures, 21% and mineral chemical compounds, 62%. The values of significant mineral commodities in Brazil's international trade are given in the following tabulations, in million U.S. dollars. In most cases, only those commodities with values exceeding $1.0 million have been included.

Mineral exports	1975	1976	1977	Percent change from 1976 to 1977
Iron ore	920.9	995.5	907.2	-9
Steel and ferroalloys	184.5	247.9	286.4	+16
Petroleum derivatives	95.9	21.7	55.9	+158
Manganese ore	80.6	66.0	32.1	-51
Tin, refined	24.9	14.8	27.9	+89

Brazil's chief overseas markets for mineral exports were: Japan (21%), the Federal Republic of Germany (13%), the United States (10%), Argentina (5%), and Italy (5%); the chief suppliers of mineral imports were Saudi Arabia (21%), Iraq (18%), the United States (9%), Kuwait (7%), and Iran (6%). In 1977, Japan was Brazil's major buyer of iron ore, and the United States was the leading buyer of manganese ore, columbium-tantalum concentrates, tin metal, ferroalloys, and steel products. Sweden was the principal market for tungsten concentrate (scheelite), and Saudi Arabia and Iraq were the primary suppliers of crude petroleum, which in 1977 represented 62% of all mineral imports.

Brazil and Iran signed a bilateral trade agreement effective June 30, 1977, valued at $6.5 billion over a 5-year period. Brazil agreed to almost quadruple its oil purchases from Iran to $1 billion per year. The oil will be sold at full Organization of Petroleum Export Countries (OPEC) prices. Brazil and Iran will study the formation of joint ventures to manufacture petrochemicals, fertilizers, aluminum, and iron pellets. The supply of copper to Brazil from Iran will also be studied.

Table 2.—Brazil: Exports of mineral commodities

(Metric tons unless otherwise specified)

Commodity	1975	1976	1977[p]	Principal destinations, 1976
METALS				
Aluminum:				
Bauxite and concentrate	17,777	2,738	3,654	Argentina 2,083; Uruguay 430.
Oxide (alumina) and hydroxide[1]	1,563	69	145	Uruguay 40; Argentina 20; Paraguay 9.
Metal including alloys:				
Unwrought	14	--	--	
Semimanufactures	r588	522	1,010	Chile 169; Peru 153; El Salvador 89; Paraguay 57.

Semimanufactures:				
Bars, rods, angles, shapes, sections	[r]65,227	101,267	217,029	Nigeria 30,328; United States 24,332; Syria 15,064; Puerto Rico 13,756.
Universals, plates, sheets	[r]37,606	37,011	15,494	United States 15,223; Argentina 10,698; Uruguay 8,531.
Hoop and strip	800	572	651	Bolivia 258; Paraguay 150; Uruguay 104.
Rails and accessories	1,064	497	71	Peru 357; United States 139.
Wire	[r]2,282	5,360	1,838	Colombia 2,476; Venezuela 899.
Tubes, pipes, fittings	[r]13,761	31,612	30,186	Uruguay 12,044; United States 5,809; Bolivia 2,743.
Castings and forgings, rough	[r]1,008	610	175	Bolivia 487; West Germany 79.
Lead metal including alloys, all forms	2	[r]5	3	Paraguay 4.
Manganese:				
Ore and concentrate thousand tons	[r]1,558	[r]1,073	560	United States 375; Norway 159; United Kingdom 110.
Oxide	1,179	[r]1,077	1,090	Argentina 873; Colombia 150.
Mercury 76-pound flasks	(2)	[r]1	--	All to Bolivia.
Molybdenum metal including alloys, all forms kilograms	23	12	445	All to Mexico.
Nickel metal including alloys, all forms	11	4	10	Argentina 3.
Platinum-group silver and metals including alloys:				
Platinum group troy ounces	219,750	112,335	1,800	Spain 105,904.
Silver do	218,368	135,708	--	Mainly to Spain.
Rare-earth metals:				
Ores and concentrates, except monazite	849	--	NA	
Oxides	3	1,090	NA	Austria 649; United States 199; United Kingdom 150.
Cerium metal including alloys	212	46	NA	Belgium-Luxembourg 37; Argentina 5; Finland 4.
Tin metal including alloys, all forms	3,494	[r]1,848	2,226	United States 1,271; Argentina 338.
Titanium:				
Ore and concentrate	63	4	13	All to Argentina.
Oxide kilograms	20	140	105	All to Venezuela.
Metal including alloys, all forms do	[r]52	156	116	NA.
Tungsten:				
Ore and concentrate	1,411	1,044	1,354	Netherlands 481; Sweden 365; West Germany 147.
Metal including alloys, all forms	25	8	16	Sweden 6; Mexico 1; United States 1.
Zinc:				
Ore and concentrate	8,510	[r]7,067	6,128	All to France.
Oxide	13	100	22	United States 85; Mexico 15.
Metal including alloys, all forms	[r]1	[r]25	44	NA.

Table 2.—Brazil: Exports of mineral commodities —Continued

(Metric tons unless otherwise specified)

Commodity	1975	1976	1977[p]	Principal destinations, 1976
METALS —Continued				
Other:				
Ores and concentrates	[r]3,729	4,884	632	West Germany 1,510; United States 1,153; United Kingdom 1,075; Japan 662.
Ash and residue containing nonferrous metals	222	761	109	Netherlands 587; West Germany 155.
Oxides, hydroxides, peroxides of metals	[r]57	12	1	West Germany 10; Mexico 2.
Metals including alloys, all forms:				
Pyrophoric alloys	12	189	481	Sweden 65; West Germany 39; Belgium-Luxembourg 22.
Waste and sweepings of precious metals	[r](4)	--	NA	
NONMETALS				
Abrasives, natural, n.e.s.:				
Emery	1	(3)	4	NA.
Grinding and polishing wheels and stones	[r]340	361	635	Singapore 60; Chile 49; Philippines 40; Ecuador 37.
Asbestos	1	(3)	6	All to Mauritania.
Boron materials: Oxide	--	--	(3)	
Cement	46,738	[r]51,641	27,778	Bolivia 36,578; Guyana 15,000.
Clays and clay products (including all refractory brick):				
Crude:				
Bentonite	1,160	600	555	All to Bolivia.
Kaolin	2,845	815	11,470	Mainly to Uruguay.
Other	1,416	475	NA	Uruguay 220; Mexico 216.
Products:				
Refractory (including nonclay brick)	[r]8,704	9,954	9,748	Argentina 4,873; Poland 4,503.
Nonrefractory	30,472	25,569	25,553	Paraguay 16,666; Bolivia 2,573.
Diamond:				
Gem, not set or strung carats	3,875	1,045	--	Belgium-Luxembourg 405; United States 355; Austria 135.
Industrial do	10,570	550	--	Argentina 240; United States 200; Japan 110.
Fertilizer materials:				
Manufactured:				
Nitrogenous	[r]500	30	1	All to Paraguay.
Phosphatic	100	--	450	
Potassic	--	[r](3)	24	All to Bolivia.
Other, including mixed	[r]8,141	8,358	2,060	Uruguay 7,747; Paraguay 611.
Ammonia	121	[r]151	196	Uruguay 126; Paraguay 23.
Fluorspar	11,075	[r]203	1,419	Mainly to Argentina.
Graphite, natural	66	195	1,133	United Kingdom 111; Argentina 53; Spain 20.
Lime	38	38	730	Bolivia 31; Paraguay 7.
Magnesite	40,237	27,919	63,788	Argentina 10,491; Poland 9,000; Peru 2,700.
Mica:				
Crude including splittings and waste:				
Lepidolite	4,146	[r]1,187	1,955	All to Japan.
Other	1,100	[r]2,800	NA	Norway 1,105; United States 1,001.
Worked including agglomerated splittings	(3)	2	(3)	Mainly to United States.
Pigments, mineral: Iron oxides, processed	38	26	NA	Paraguay 24; Bolivia 2.
Precious and semiprecious stones, except diamond, crude and worked:				
Agate kilograms	2,465,994	1,929,158	1,346,803	Japan 745,928; United States 532,980; West Germany 485,359.
Amethyst do	[r]248,815	182,324	202,338	West Germany 58,824; France 39,865; United States 32,224; Italy 18,567.
Aquamarine do	1,438	559	1,179	West Germany 235; Japan 188; United States 61.
Cat's eye do	1	1	1	Mainly to Japan.
Citrine do	24,049	24,250	33,830	France 9,282; Japan 6,453; West Germany 4,378.
Emerald do	[r]2,302	2,991	2,266	United States 1,302; India 528; Hong Kong 473; Switzerland 340.
Garnet do	307	211	177	West Germany 193.
Opal do	77	513	342	Australia 330; United States 129; Hong Kong 51.
Sapphire do	[r](3)	(3)	(3)	NA.
Topaz do	2,714	4,743	3,850	France 1,669; United States 1,517; West Germany 1,182.

Table 2.—Brazil: Exports of mineral commodities —Continued

(Metric tons unless otherwise specified)

Commodity	1975	1976	1977[p]	Principal destinations, 1976
NONMETALS —Continued				
Precious and semiprecious stones, except diamond, crude and worked —Continued				
Tourmaline ____ kilograms	422	2,838	526	France 1,847; Japan 755.
Turquoise ____ do	101	(2)	(2)	NA.
Other ____ do	436,944	742,433	524,602	West Germany 211,838; Japan 182,910; United States 78,413; Hong Kong 76,796.
Quartz crystal:				
Electronic and optical grade	1,672	1,965	NA	U.S.S.R. 567; Japan 417; United States 304; West Germany 261; Netherlands 195.
Other	177	73	NA	Japan 32; Hong Kong 16; France 11; West Germany 8; Austria 5.
Salt	32,421	1	(2)	All to Bolivia.
Sodium and potassium compounds, n.e.s	7,777	5,328	4,153	Argentina 4,750; Paraguay 570.
Stone, sand and gravel:				
Dimension stone:				
Crude and partly worked	25,635	19,158	57,453	Italy 10,485; Japan 4,960; Spain 2,139.
Worked	8,355	15,838	7,607	Italy 7,157; Japan 7,155.
Dolomite, chiefly refractory grade	558	875	797	Argentina 725; Colombia 150.
Quartz and quartzite	192	17	1,610	All to Netherlands.
Sand, excluding metal bearing	1,934	2,763	996	Mainly to Paraguay.
Sulfuric acid, including oleum	90	289	400	Do.
Talc, steatite, soapstone, pyrophyllite	209	247	189	Argentina 108; Paraguay 72; Colombia 42.
Vermiculite	1	--	45	
Other:				
Crude	90	(2)	874	Mainly to Bolivia.
Slag, dross, and similar waste, not metal bearing, from iron and steel manufacture	15	--	--	
Building materials of asphalt, asbestos, and fiber cement, and unfired nonmetals, n.e.s	r1	35	6,214	Paraguay 28; Bolivia 7.
MINERAL FUELS AND RELATED MATERIALS				
Carbon black	6	12	3	Bolivia 8; Paraguay 4.
Coal and briquets	27	58	234	Paraguay 50; Uruguay 8.
Hydrogen and rare gases ____ kilograms	1,891	2,667	2,298	Mainly to Uruguay.
Petroleum:				
Crude and partly refined thousand 42-gallon barrels	8,079	r19,219	12,011	Argentina 9,011; Peru 6,769; Bahamas 3,209.
Refinery products:				
Gasoline, motor ____ do	r1,521	124	1,572	Mainly to Peru.
Kerosine ____ do	r400	16	177	Do.
Distillate fuel oil ____ do	2,975	715	1,348	Argentina 489; Peru 226.
Residual fuel oil ____ do	2,156	465	208	Uruguay 209; Bahamas 164; Paraguay 92.
Lubricants ____ do	r7	18	14	Paraguay 11; West Germany 4; France 2.
Mineral jelly and wax ____ do	3	(2)	6	Mainly to Mauritania and Bolivia.
Other:				
Liquefied petroleum gas ____ do	804	75	203	All to Surinam.
Nonlubricating oils ____ do	34	1	18	Mainly to Paraguay.
Pitch ____ do	15	--	18	
Petroleum coke ____ do	5	2	--	All to Paraguay.
Bitumen ____ do	71	--	135	
Bituminous mixtures ____ do	1	2	5	Mainly to Paraguay.
Unspecified ____ do	(4)	--	(2)	
Total ____ do	r7,992	1,418	3,704	
Mineral tar and other coal-, petroleum-, or gas-derived crude chemicals	116	82	757	Paraguay 62; Uruguay 20.

[p]Preliminary. [r]Revised. NA Not available.
[1]Includes alumina gel.
[2]Less than 1/2 unit.
[3]Includes some tantalum.
[4]Revised to none.

COMMODITY REVIEW

METALS

Bauxite, Alumina, Aluminum.—Output of bauxite increased 35% to a record high. Most production came from mines in the State of Minas Gerais operated by Companhia Mineira de Aluminio (ALCOMINAS), Alcan Aluminio do Brasil S.A. (ALCAN), and Companhia Brasileira de Aluminío (CBA). Construction continued on the Trombetas bauxite project in the Amazon basin under a consortium of Brazilian, Dutch, Norwegian, Spanish, and U.S. companies, which comprise Mineração Rio do Norte S/A. Initial production, at a rate of 1.4 million tons per year, was expected by early 1979. Trombetas deposit discovered in 1967 has an estimated 600 million tons of

Digitized by Google

the trihydrate form of bauxite with an average alumina content of 55%; trihydrate is more economical to process than the monohydrate form.

Other bauxite deposits in the Amazon region contain an additional 2 billion tons of ore, and exploitation plans are in various stages. As of yearend 1977, DNPM reported an 11% increase in total Brazilian measured reserves of bauxite, which totaled 1.93 billion tons grading 55% Al_2O_3 located chiefly in the Amazon region.

Alumina totaling 345,000 tons was produced by three Brazilian companies—CBA, ALCAN, and ALCOMINAS—utilizing bauxite from their mines in Minas Gerais. Aluminio do Norte SA (ALUNORTE), a joint venture of CVRD and a 32-company Japanese group, was developing a $500 million, two-stage alumina plant near Belém, Pará. First-stage output of 800,000 tons per year of alumina was planned for 1983, with the second-stage output of 1.2 tons projected for 1985. Most of ALUNORTE's production was destined for the associated aluminum smelter of Aluminio Brasileiro SA (ALBRAS).

Although production of primary aluminum increased 20% to a record high, it was still necessary for Brazil to import primary aluminum. In 1977, 62,000 tons of primary aluminum valued at $91.2 million was imported principally from the Federal Republic of Germany and the Republic of South Africa. All three aluminum producers, CBA, ALCAN, and ALCOMINAS, were involved in major expansion projects to increase capacities as indicated in the following tabulation, in thousand tons:

	1977	1980	1985
CBA	48	90	120
ALCAN	60	88	138
ALCOMINAS	60	90	120
Total	168	268	378

Three other primary aluminum smelters were under development or in advanced planning stages as listed in table 4. ALBRAS, the largest project, is a joint venture of CVRD and Japanese interests. Its aluminum production will be marketed in Brazil (51%) and in Japan (49%).

Table 4— Brazil: New aluminum smelters under development

Company	Smelter location	Annual capacity (thousand tons)	Startup date	Project cost (million U.S. dollars)
ALBRAS	Belem, Para	[1]40	1983	1,100
Aluminio do Sul S/A (VELESUL)	Rio de Janeiro	80	1981	248
ALUNORTE	Recife, Pernambuco	80	1986	NA

NA Not available.
[1]ALBRAS' planned capacity for 1987 is 320,000 metric tons per year.

Chromium.—Although mine production of chromite decreased 23%, output of chromium concentrate increased 89% to a record high. Exports of concentrate increased sharply from 9,128 tons in 1976 to 71,111 tons in 1977 and were shipped entirely to Japan. Brazil exported 46,661 tons of ferrochromium valued at $19 million, the country's second most valuable ferroalloy traded after ferrocolumbium.

Columbium.—Brazil remained the world's largest producer of columbium minerals. Pyrochlore ore production increased to a record high of 796,000 tons, but the concentrate of Nb_2O_5 decreased 18% to 15,613 tons. There were only two pyrochlore producers in 1977—Companhia Brasileira de Metalurgia e Mineração (CBMM), which produced 13,082 tons of concentrate from its mine at Araxá, Minas Gerais; and the recently established Mineração Catalão de Gerais S/A, which produced 2,531 tons of concentrate at Ouvidor, Goiás. The Cia. de Estanho São Joáo Del Rey produced tantalite and columbite ore and concentrate.

Exports of ferrocolumbium declined 23% to 7,052 tons, but its value of $42.3 million made ferrocolumbium Brazil's most valuable ferroalloy export. Major markets for ferrocolumbium in 1977 were the United States (34%), the Low Countries (21%), and Japan (12%).

Copper.—Brazil continued to depend entirely on imports to meet its demand for primary copper. Imports of primary copper in 1977 increased 21% to 182,439 tons at a

Digitized by Google

cost of $265 million. The electrolytic copper came primarily from Chile (88%) and Peru (9%). Secondary copper production from scrap totaled 45,900 tons, an increase of 17% over that of 1976. At yearend, measured copper reserves increased 18% to 53 million tons of ore with an average grade of 1.2%.

The Eluma Corporation, a private group based in São Paulo, received Government permission to construct a 150,000-ton-per-year smelter in the State of Rio Grande do Sul. The smelter, to be supplied from imported concentrate, was planned for startup in 1982 with full-capacity production by 1985. Work continued on the Caraíba Metais S/A in Bahia, a $775 million mine, smelter, and refinery complex planned for startup in 1981 with a capacity of 100,000 tons per year of refined copper.

Gold.—According to DNPM, the 4-year downtrend in gold production was reversed in 1977, but production was less than the 1972 high of 231,000 troy ounces. Of total production, 30% came from "garimpeiros," numerous independent prospectors operating principally in the Amazon region. Data published by Consolidated Gold Fields Ltd. show that Brazil produced 12,900 kilograms or 415,000 troy ounces of gold in 1977 and became the largest producer in Latin America. This figure includes an estimate of output by the garimpeiros not registered through sales at the Government agencies. The only industrialized mine operating was that of Mineração Morro Velho S/A near Belo Horizonte, Minas Gerais, which began operating in 1725 with extraction carried out continuously since 1834. In March 1975, the Anglo-American Corp. purchased a 49% interest in the Morro Velho complex.

CVRD initiated experimental mining of gold deposits in the Serra das Andorinhas in the State of Pará near the giant Carajás iron ore deposit, considered by DNPM to be one of the most important mineral discoveries of 1977.

Iron Ore.—A major event in 1977 was the startup of the $600 million project, Samarco Mineração S/A, a joint venture of S.A. Mineração Da Trinidade (SAMITRI) (50%) and Utah International Co., (49%). The SAMARCO project consisted of mining and concentrator facilities at the Germano mine site southeast of Belo Horizonte, a 396-kilometer slurry pipeline, and a pellet plant and ocean terminal at Ponta Ubu, 80 kilometers south of the port of Vitória, State of Espirito Santo. Average iron content of the Germano itabirite ore is 53% and it is concentrated up to 67.5%. Reserves of at least 150 million tons of ore minable by open pit methods have been established.

Capacity of the SAMARCO operation provides for 5 million tons per year of pellets and 2 million tons of pellet feed, although the pipeline was engineered to permit expansion to 12 million tons per year. The ocean terminal accommodates vessels up to 150,000 deadweight tons and may be expanded up to 250,000 deadweight-ton capacity. In its initial year of operation, SAMARCO exported 1.6 million tons of iron ore.

At yearend, arrangements had been finalized for CVRD, with 51% of the Carajás project, to purchase the 49% remaining equity held by United States Steel Corp. through its Brazilian subsidiary, Companhia Meridional de Mineração. CVRD reportedly intends to develop the Carajás project through Amazonia Mineração S/A at the reduced level of 5 million tons per year. The project includes construction of a 890-kilometer railroad to link the deposit to a projected port complex near Itaqui in the State of Maranháo. The Carajás deposit in the Amazon basin has an estimated 18 billion tons of high-grade iron ore containing 66% iron, the largest known single deposit of iron ore in the world. The major achievements during 1977 of CVRD, Brazil's dominant producer and exporter of iron ore, included completion of double-tracking of its 550-kilometer railroad used to haul iron ore from CVRD and other mines in the "Iron Quadrangle" to the ports of Tubarão and Vitória. Also, a new pellet plant was inaugurated at Tubarão of Cia. Italo-Brasileira de Pelotizacão (ITABRASCO), a joint venture of CVRD and the Italian Societá Finanziaria Siderurgica S.p.A. (Finsider). ITABRASCO's pellet production of 3 million tons per year will be used chiefly to supply the European market. With this addition, CVRD's total pellet capacity increased to 8 million tons. In 1977, CVRD produced 3.5 million tons of iron ore pellets, compared with 4.7 million tons in 1976.

CVRD's production of 42.8 million tons of ore in 1977 represented 52% of Brazil's total; its exports were 68% of the total. Although CVRD's iron ore sales in foreign markets decreased 17%, sales to the domestic market increased 84% to 5.9 million tons. Domestic consumption totaled 13.4 million tons for the year. CVRD signed contracts with Japanese steel plants for sale

Digitized by Google

of iron ore amounting to $1.3 billion with deliveries scheduled to begin in 1979. At yearend, CVRD had sales commitments amounting to 609 million tons on a long-term basis, mostly in Asia and Western Europe.

At yearend, DNPM reported Brazil's total iron ore reserves at 32.4 billion tons, of which 9.9 billion tons was measured reserves.

Table 5.—Brazil: Production and exports of iron ore

Year	Production[1] (thousand metric tons)	Exports			
		Quantity (thousand metric tons)	Percent change from previous year	Value (thousands)	Average export price[2] (per metric ton)
1968	24,532	15,050	+5	$104,450	$6.94
1969	27,571	21,478	+43	147,400	6.86
1970	36,381	27,943	+30	209,600	7.50
1971	37,486	31,020	+11	237,000	7.64
1972	46,471	30,512	-2	231,708	7.59
1973	55,019	44,963	+47	362,811	8.08
1974	76,071	59,439	+32	571,159	9.74
1975	89,894	72,522	+22	920,891	12.92
1976	94,087	67,188	-7	995,473	15.15
1977	[3]82,001	[4]58,541	-13	907,247	15.51

[1]Data for years prior to 1972 cover crude or run-of-mine ore; those for 1972 and subsequent years cover beneficiated ore plus ores of direct-shipping grade.
[2]Based on CVRD price data beginning with 1973.
[3]Output of beneficiated ore was 80,935,691 tons.
[4]Destinations were Japan (33%), West Germany (19%), and France (7%).

Iron and Steel.—As a steel producer, Brazil ranked 14th worldwide and remained the leader in Latin America. The strong, uninterrupted upward trend of more than a decade continued in 1977 with a 22% increase in crude steel production to 11.2 million tons. Paralleling this favorable trend was the increase in output of ferroalloys to more than 371,000 tons, a 19% increase. The five major steel companies that produced more than one-half million tons of crude steel in 1977 are listed in the following tabulation:

Company	Output (thousand tons)	Percent change over prior year
Usinas Siderúrgicas de Minas Gerais (USIMINAS)	2,721	+16
Cia. Siderúrgica Nacional (CSN)	1,962	+44
Cia Siderúrgica Paulista (COSIPA)	1,539	+95
Cia Siderúrgica Belgo-Mineira	800	+1
Mannesmann S.A	601	+7
Total	7,623	--

Exports of steel products totaled $67 million.

Brazil also continued to decrease its dependence on imports of finished and semifinished steel products valued in 1977 at $660 million, compared with the peak year of 1974 when products valued at $1.7 billion were imported.

Since 1976, Brazil's largely Government-owned steel industry has continued to experience difficulty in obtaining adequate project financing. Private steel companies suffered from low, Government-controlled steel prices and increased costs of raw materials. Nonetheless, Brazil's three major steel makers, CSN, Usinas Siderúrgicas de Minas Gerais (USIMINAS) and Companhia Siderugica Paulista (COSIPA) proceeded with their phased development objectives. CSN, Latin America's oldest and largest steel facility, completed its phase 2 expansion up to a capacity of 2.5 million tons of crude steel per year, and proceeded with its phase 3 program to expand capacity up to 4.8 million tons by 1983. In 1977, USIMINAS was completing arrangements to finance its phase 3 expansion and shelved its plans to install a direct reduction facility. USIMINAS arranged with its Japanese associates to increase the company's authorized capital to $278 million, requiring

Digitized by Google

additional contributions of the Japanese to maintain their 18.5% share in the operations. COSIPA expected to complete phase 2 expansion to 2.3 million tons per year in 1978 instead of in 1977.

A new company, Aço de Minas Gerais S/A (ACOMINAS), began construction in June 1977 of a $3.4 billion project in Ouro Branco, Minas Gerais, designed to produce 2.2 million tons of steel by 1981. As a result of these and other expansion plans, Brazil was expected to become self-sufficient in steel by the early 1980's. Siderúrgica Brasileria S/A (SIDERBRAS), the holding company for Brazil's Government-owned steel plants, decided to delay phase 4 expansion and was developing a coherent plan for the whole steel sector.

At yearend, plans had not been finalized on the initial output of the proposed Tubarão steel mill to be located at the port of Tubarão, Espirito Santo, the site of CVRD's massive iron ore pelletization complex. The Tubarão mill, a joint venture of CVRD, Finsider of Italy, and 14 Japanese companies led by Kawasaki, was originally programed to produce 3 million tons of slabs or semifinished steel by 1980.

Lead.—The rebound in the lead content of mined ore continued since the depressed level of 1975 but fell short of the peak year of 1972 when 29,880 tons was mined. However, output of primary lead from domestic and imported concentrate reached a record high of about 48,303 tons, an increase of 11%. Imports of lead concentrate that came entirely from the U.S increased 70% to 42,600 tons.

Lead ore was mined by two companies controlled by the Brazilian Peñarroya Group—Mineração Boquira S/A from mines in Bahia and PLUMBUM S/A from mines in the Paraná-São Paulo lead district. Other operations controlled by Peñarroya were being expanded to increase capacity for smelting and refining lead as indicated below, in metric tons:

Company	Smelter-refinery location	Current capacity	Planned capacity	Startup date
PLUMBUM S/A	Adrianopolis, São Paulo.	18,000	30,000	1981
Cia Brasileira de Chumbo (COBRAC)	Salvador, Bahia	32,000	45,000	1980
Total		50,000	75,000	--

Manganese.—DNPM reported a 47% drop in exports of manganese ore during 1977 to 571,200 tons. The value of exports declined 50% to $33 million. Industria e Comercio de Minerios S/A (ICOMI) remained the largest producer and exporter of ore. ICOMI produced 110,000 tons of pellets, a 10% increase.

As shown in the following tabulation, output has been increasing from the relatively new mining area of Urucum in the State of Mato Grosso where three companies are involved—Urucum Mineração S/A, Mineração Mato Grosso, and Sociedade Brasileira de Imóveis LTDA (SOBRAIMOVE).

State or territory	Gross production (thousand metric tons)		Percent change from 1976 to 1977
	1976	1977	
Amapá	2,113	1,634	-23
Minas Gerais	602	769	+28
Mato Grosso	50	236	+372
Bahia	73	71	-3
Goiás	34	26	-24
Espírito Santo	10	1	--
Total[1]	2,881	2,737	-5

[1]Data may not add to totals shown because of independent rounding.

Digitized by Google

The Cia Mineira de Mineração acquired the manganese property at Conselheiro Lafaiete, Minas Gerais, from Cia Meridional de Mineração S/A, a subsidiary of United States Steel Corp. In the State of Pará, CVRD was actively investigating the economic feasibility of developing the manganese occurrence near the Carajás iron ore deposit, which is estimated at over 40 million tons of ore grading from 39% to 46% manganese.

Domestic consumption of manganese ore amounted to 137,430 tons compared with 116,370 tons consumed in 1976.[3] Combined production of ferromanganese and ferrosilicomanganese increased 25% to 204,000 tons, of which 39,330 tons was exported. Brazil's measurod manganese reserves at yearend were reported by DNPM to have increased 10% to 55.7 million tons grading 40% manganese.

Silver.—Brazil has not been a significant producer of silver. In 1977, silver was recovered mostly as a byproduct of lead in Paraná and, to a smaller extent, as a byproduct of gold in Minas Gerais. Silver output increased sharply in 1977 to about 372,000 troy ounces, but production was still significantly below the 1971 high of 627,000 troy ounces.

DNPM reported a great increase in measured reserves of silver to 6.4 million tons of ore, with 5,981,000 tons grading 0.74 troy ounce of silver per ton located in Guajará-Mirim, Rondonia, and 365,000 tons grading 1.93 troy ounces per ton in Adrianópolis, Paraná. Total silver content of the reserves was estimated at 5.24 million troy ounces.

Tin.—Brazil's production of tin ore (cassiterite) and tin metal achieved record highs in 1977. The Rondonia tin district accounted for 63% of Brazil's output of cassiterite. Imports of tin concentrate, which increased 162% in quantity and 230% in value, came from Bolivia (56%) and Singapore (38%). The amount of concentrate imported was equal to 41% of the country's production. Within the nonferrous group, refined tin was the only commodity produced by Brazil from domestic and imported concentrate, with a surplus available for export. The country's apparent consumption of tin in 1977 was 4,800 tons. Brazil exported 2,100 tons of primary tin mostly to the United States (77%) and Argentina (11%). Table 6 shows that Brazil had a smelter capacity that exceeded its domestic and export demands for metallic tin. At yearend, Brazil's measured tin reserves increased 9% with a metal content of 56,200 tons. The discovery of an important cassiterite-bearing granite was reported 40 kilometers north of São Félix do Xingu in the State of Pará. CPRM continued its study of the tin potential of the Rondonia tin district started in September 1976.

Table 6.—Brazil: Major tin smelters

(Metric tons)

Smelter	Location	Production capacity	1977 ingot production
Cia. Estanifera do Brasil S/A (CESBRA)[1]	Volta Redonda, Rio de Janeiro.	6,800	3,700
Cia. Industrial Amazonese S/A (CIA)[1]	Manaus, Amazonas.	4,800	1,100
Mamorá Mineração e Metalurgia Ltd	São Paulo	3,000	1,700
Best Metais e Soldas S.A.	São Paulo	1,200	400
Cia. Industrial Fluminense S/A (BRASCAN)	São João del Rei, Minas Gerais.	1,200	400
Bera do Brasil S/A	São Paulo	1,200	100
Total		18,200	7,400

[1]Also using imported concentrate of tin.

Source: National Association of Tin Producers.

Tungsten.—Output of scheelite concentrate increased 20% to a record high of 2,026 tons. The flat output trend was broken in April 1977, with the beginning of operations of the underground mine at Currais Novas, Rio Grande do Norte, of Mineração Tungstenio do Brasil (MTB). MTB's $7.5 million operation has a capacity of 600 tons per year of concentrate containing 73% WO_3.

The quantity of tungsten concentrate exported in 1977, valued at $15.2 million, increased 30% and was shipped primarily to Sweden (42%), the Low Countries (23%), and France (17%). Production of ferrotungsten increased to 141 tons com-

Digitized by Google

pared with 15 tons produced in 1976, but was below the peak year of 1973 when 195 tons was produced.

The Government created an Interministerial working group in 1977 to investigate the feasibility of a tungsten metal-ferrotungsten plant to be located in Rio Grande do Norte. Brejuí Mineração e Metalurgia S/A was constructing a plant to process the tailings of Mineração Tomaz Salustino S/A, an important tungsten miner in the Currais Novos district. MTB's second shaft at its Boca de Lage mine will enable the company to double its output by early 1980's to 14,000 tons of ore per month.

Zinc.—Despite an impressive increase in mine output of zinc ore in Minas Gerais from 20,000 tons in 1969 to 458,000 tons of ore in 1977, Brazil continued to depend strongly on imports to satisfy internal demand for primary zinc. Imports of primary zinc represented 52% of the country's demand for zinc, estimated at 113,000 tons, a 12% increase over demand in 1976. Electrolytic zinc ingots came mostly from Mexico (60%) and Peru (32%).

The Cia. Mineira de Metais S/A (CMM), which operated Brazil's largest zinc smelter at Vazante, Minas Gerais, was expanding its capacity to 50,000 tons of slab zinc per year by 1978, with further expansion planned to 75,000 tons per year by 1979. Brazil's total smelter capacity by 1978 was to be 64,000 tons. Cia. Paraibuna de Metais S/A was constructing a smelter complex at Paraibuna, Minas Gerais, with initial output expected to be 26,500 tons of zinc in early 1979. Union Minière of Belgium has a 14.5% interest in this Brazilian company.

NONMETALS

DNPM reported substantial increases in the measured reserves of slate (280%), graphite (106%), phosphate rock (53%), kaolin (50%), lithium minerals (50%), limestone (25%), quartz (23%), and fluorspar (14%).

Asbestos.—Brazil imported about one-fourth of its asbestos requirements. The growth in production of crude asbestos and fiber has been impressive over the decade; output of ore was 1.5 million tons in 1977 compared with 171,500 tons in 1968; by 1977, Brazil ranked eighth worldwide and was the leading producer in Latin America. The main producer was S/A Mineração de Amianto (SAMA), whose Cana Brava mine is located at Minaçu, Goiás, 270 kilometers northwest of Brasilia. SAMA's output in 1977 totaled 90,224 tons of fiber and was planning to reach 115,000 tons by 1979. A smaller producer, Cimento Amianto S/A (PERMETEX), produced 1,570 tons of asbestos fiber at Barro Alto, Goiás.

Clays.—*Bentonite.*—Brazil's production of bentonite solely from reserves at Campina Grande in the State of Paraíba in the Northeast experienced steady growth during the past decade when output grew from 13,000 tons in 1968 to 143,000 tons in 1976. In that year, Brazil became Latin America's leading producer. However, in 1977, output declined 24%.

Kaolin.—Output of beneficiated kaolin, largely ceramic grade, increased 244% to about 260,000 tons. Kaolin was mined in 12 States and Territories of Brazil with beneficiated output mostly from São Paulo, Minas Gerais, and Amapá. Caulim da Amazonia Ltd. of the Ludwig Group began production during 1977 of a coating clay plant, located at Munguba on the west bank of Rio Jari in Pará, with a capacity of 220,000 tons per year to process the mineral from the Felipe deposit across Rio Jari. Caulim do Pará S/A continued to develop a project in the Capim area of Pará with a capacity of 288,000 tons per year.

Fertilizer Materials.—During the past decade, Brazil achieved considerable reduction in its dependence on foreign sources of fertilizer materials. Mined output of phosphate rock, for example, increased from 53,000 tons of contained P_2O_5 in 1968 to 650,000 tons in 1977. Nonetheless, during 1977 Brazil imported natural phosphate rock, manufactured phosphatic material, and nitrogenous and potassic fertilizers valued at $352 million. In early 1977, construction began on a $38 million phosphate mining project designed to extract 2.2 million tons per year of phosphate rock from reserves near Catalão in the State of Goiás. A new company, Fosfatos de Goiás S/A (FOSFAGO), is a joint venture of the Brasimet Group (51%), an affiliate of South American Consolidated Enterprises Inc. and the Williams Companies (49%). The open pit mine and concentrate plant was scheduled for completion by yearend 1978.

In February, a new subsidiary of PETROBRAS was created, Petrobras Mineração S/A (PETROMIN), to engage in mineral production and marketing, particularly of the large potassic reserves of Sergipe in the Northeast. In November, Enterprise Minière et Chimique (EMC) signed an agreement with PETROMIN under which Mines de Potasse d' Alsace (MDPA) will provide

Digitized by Google

technical assistance and prepare a feasibility study on mining and processing methods for the potash deposits at Carmopolis in Sergipe.

Vermiculite.—Exploration interest was high as a result of international energy problems and vermiculite's special applications in the insulation industry. Output of crude vermiculite from the Paulistana area of Piauí and São Luiz dos Montes Belos in Minas Gerais increased remarkably from about 950 tons in 1976 to about 6,800 tons in 1977, making Brazil the leading producer in Latin America. Metais de Goiás S/A (METAGO), which is the Goiás State mining company, and Elf-Aquitaine of France entered into a joint venture to develop a vermiculite deposit at Catalão estimated to have reserves of 48 million tons. A facility to produce 30,000 tons per year of vermiculite concentrate was contemplated. Most of the output would go to Elf-Aquitaine plants in Europe.

MINERAL FUELS

Coal.—With coal output held relatively steady over the past decade, production of run-of-mine coal increased in 1977 by 44% to about 10 million tons, while marketable coal increased 10.2% to 3.6 million tons. Production of steam coal in Santa Catarina, Rio Grande do Sul, and Paraná has grown steadily to 2.8 million tons in 1977. Consumption of steam coal in 1977 was 1.9 million tons.

Despite a 24% increase in the output of metallurgical coal to 1 million tons, it was necessary to import 3.6 million tons of coal at a cost of $236 million. Imports represented 78% of the 4.6 million tons of coking coal consumed in Brazil in 1977 and came mostly from the United States (58%) and Poland (32%). Coke consumed by the Brazilian iron and steel industry amounted to 3.6 million tons, and charcoal consumed was 6.8 million tons. Consumption of metallurgical coal was expected to grow to 16 million tons in 1985, of which 12.8 million tons would be imported. Production of steam and metallurgical coal was projected to grow to 10.4 million tons by 1987.

The Companhia Riograndense de Mineração (CRM), owned by the State of Rio Grande do Sul, was carrying out a $50 million project to increase output from its Leão mine to 2 million tons of steam coal per year by the early 1980's. The output will be used to provide energy and feedstocks for a $400 million coal gasification plant being planned by PETROBRAS in Rio Grande do Sul. A working group of PETROBRAS completed a study of the gasification processes available, and preliminary negotiations were opened up with two Federal Republic of Germany engineering firms on licensing arrangements for a suitable process.

In addition to the coal reserves in southern Brazil, deposits have been discovered in the Amazon basin where large quantities of coal are believed to exist. However, difficult mining conditions, the absence of infrastructure, and remote location from consumption centers make the mining of Amazonian coal not feasible for the near future.

Natural Gas.—Production of natural gas increased 10%, reaching a record high of 63.8 billion cubic feet. Output has grown unevenly since 1968 when the amount produced was 34.7 billion cubic feet. Output of natural gas valued at $47 million represented only 1.6% of Brazil's total mineral output. Consumption of natural gas increased 38% during 1977, and the value of imports increased 57%. Negotiations continued between Brazil and Bolivia on the sale of gas from Bolivia's Santa Cruz gasfields and construction of the required 640-kilometer gas pipelines to the Brazilian border. At yearend, reserves of natural gas increased 16% to 1,400 billion cubic feet.

Oil Shale.—PETROBRAS continued experimental operation of its 1,000-barrel-per-day pilot plant using oil shale from the deposit of São Mateus do Sul in the State of Paraná to obtain data for a future industrial plant. In October 1975, the Government announced it would build a 53,000-barrel-per-day oil shale recovery plant at São Mateus do Sul. In 1977, the Government authorized the Superintendent for the Industrialization of Oil Shale (SIX) to proceed with the medium-term program of developing a detail project within the next 3 years for the construction of a plant at São Mateus do Sul. Geological exploration continued on the Irati oil shale formation in Paraná and on deposits in the States of Maranhão, Bahia, Ceará, and Santa Catarina.

Petroleum.—As a result of intensified exploration and development activities, PETROBRAS reported another increase in oil and gas reserves. At yearend, proven oil reserves increased 27% to 1.11 billion barrels compared with the 877 million barrels reported for 1976.

Production of crude petroleum further decreased 3.5%, continuing the downtrend

Digitized by Google

since the peak year of 1974. As shown in table 7, the substantial increase in oil output from the continental shelf did not compensate for the decline in the onshore oilfields of the Bahia area. The average rate of production of 170,000 barrels per day required Brazil to import 82% of its crude oil needs. The quantity of crude oil imported was almost equal to that of 1976, but petroleum products decreased 20%. However, the cost of these imports increased slightly to $4.2 billion, of which reexports amounted to $130 million. The average cost of crude oil during 1977 was $12.30 per barrel compared with $11.50 in 1976. Saudi Arabia (34%) and Iraq (29%) continued as the major suppliers to Brazil of crude oil.

In response to the Government's conservation policies, consumption of automobile gasoline decreased 4% while total national consumption of petroleum products increased only 2.4% compared with the 9% increase the year before. Total apparent domestic consumption for 1977 was 952,000 barrels per day, compared with 1.2 million barrels per day projected for 1977 before the energy crisis. Consumption, which grew 50% between 1970 to 1973, grew by 16% between 1974 to 1977 as a result of conservation measures.

Table 7.—Brazil: Crude oil production by PETROBRAS[1]

(Thousand 42-gallon barrels)

Area	1975		1976		1977		Percent change from 1976 to 1977
	Production	Percent	Production	Percent	Production	Percent	
Bahia	39,973	63.7	39,489	64.7	32,614	55.5	-17
Sergipe	10,039	16.0	10,165	16.7	9,988	17.0	-1
Espirito Santo	1,692	2.7	1,534	2.5	975	1.7	-36
Alagoas	994	1.6	1.566	2.5	1,101	1.9	-30
Continental Shelf	10,070	16.0	8,272	13.6	14,008	23.9	+69
Total	62,768	100.0	61,026	100.0	58,686	100.0	-4

[1]Figures given in table 1 were reported subsequently by DNPM.

Source: PETROBRAS Annual Report 1976 and 1977.

During 1977, production began from a well in the Enchova field of the Campos basin located off the coast of Espirito Santo on the Continental Shelf. The Enchova field became Brazil's major producer at the rate of 10,080 barrels per day. The temporary production system for the Campos basin, comprising three wells in the Namorado oilfield and six wells in the Garoupa, were in the final installation phase and expected to be ready in the first quarter of 1978. Total investment costs for the permanent Campos production system were estimated at $2 billion, including the installation of 5 offshore platforms linking about 70 undersea wells to pump a projected 250,000 barrels of oil per day and 3 million cubic feet of gas per day to onshore facilities. Probable reserves in the Campos basin were estimated at 650 million barrels.

Offshore exploration in Brazil was at an alltime high. By yearend 1977, PETROBRAS had spent $1 billion in offshore exploration, drilling 250 wells to obtain additional reserves of 500 million barrels of oil and 12 billion cubic feet of gas. Two of the rigs were operating for British Petroleum and Shell. In 1977, PETROBRAS initiated strategic exploration program, a multibillion dollar effort involving the drilling of 325 offshore wildcats and stepouts to determine whether the Brazilian shelf is the long-sought source of the country's self-sufficiency in energy.

In January 1977, the first round of bidding under the new risk service contract procedure came to a close with the signing of a contract with the consortium formed by Elf-Aquitaine Bresil and AGIP S.p.A. for exploration in block 2 in the mouth of the Amazon River. In April, PETROBRAS signed its fourth service contract with a risk clause with Companhia Esso Prospecção do Brasil for block 4 in the Santos basin, 60 kilometers south of Rio de Janeiro.

Under the second round of bidding, two contracts were signed in December 1977 with BP Petroleum Development Brazil Ltd. and Pennzoil do Brasil Inc. This brought to six the number of service contracts PETROBRAS has signed with multinational oil companies in the period 1976-1977 for the exploration of the Amazon and Santos basins of the Continental Shelf.

Alcohol Energy Program.—Production of anhydrous alcohol, primarily from the processing of sugar cane and manioc, was 500 million liters, representing 5% of the total motor vehicle fuel (excluding diesel fuel) used in Brazil during the year. Output of alcohol for 1978 was forecast at 2.6 billion liters. To meet the program's goal of a 20% mix with gasoline, 3.4 billion liters would be required by 1980. In December, PETROBRAS began experimental operation of an alcohol plant located in Curvelo, Minas Gerais, with a capacity of 60,000 liters per day.

Nuclear Energy.—By yearend, Brazil had not initiated industrial-scale mining or commercial beneficiation of uranium ore. A small pilot plant to produce uranium concentrate (yellowcake) was in operation at Poços de Caldas, Minas Gerais. The plant utilized small quantities of ore extracted from a nearby underground mine at Cerado. Construction continued on a 550-ton-per-year plant scheduled for late 1979 or early 1980. Initial consumption of U_3O_8 was projected at 15.4 tons in 1979, growing to 821 tons in 1987.[4] Empresas Nucleares Brasileiras S/A (NUCLEBRAS) was involved with an extensive exploration program for uranium throughout Brazil. Uranium reserves were officially revalued upwards several times during 1977. At yearend, DNPM reported a total of some 67,000 tons of U_3O_8, as shown in the following tabulation, compared with 26,000 tons of reserves reported in 1976.

The Mineral Industry of Bulgaria

By Tatiana Karpinsky[1]

In 1977, Bulgaria produced copper, iron and steel, lead, zinc, coal, crude oil, natural gas, fertilizers, cement, fluorspar, kaolin, and other mineral commodities. Byproducts recovered from some metallic ores enhanced the economic value of mining in some cases. Indigenous production of coal, gas, petroleum, and iron supplied only a small part of the country's requirements.

According to Bulgarian sources, national income in 1977 increased 6.3% (planned 8.2%). Productivity of labor went up 7% (planned 8.1%) and accounted for the overall increment in national income. In 1977, Bulgaria paid special attention to the industrial application of the results of research and development as a major factor of enhancing the efficiency of production and the quality of output. The benefits derived from the application of scientific and technological advances were valued at over 700 million leva (L).[2]

Capital investments totaled L5.3 billion in 1977. About 68% was for renovation and development of existing industrial facilities, compared with 54% in 1976. In 1977, according to Bulgarian sources, gross industrial production increased 7% (planned 9.2%). Mechanical engineering, chemicals, iron and steel, and power generation accounted for 46.6% of total State industrial production, and ferrous and nonferrous metallurgy provided some 6%.

The following percentage increases were reported for 1977 production: Pig iron, 3.6; crude steel, 5.2; rolled steel, about 7; and electric energy, 7. Total coal production declined about 1%.

The total number of industrial workers and employees in State enterprises was 1,192,000 in 1976. The number of workers and employees in State mineral and energy enterprises by branch is given in the following table:[3]

Branch	Workers and employees (thousands)
Fuel industry	50.8
Ferrous metallurgy (including ore mining)	31.7
Engineering and metalworking industry	329.0
Production of electricity and steam heat and power	20.3

In 1977, the State Council issued a decree reorganizing the existing Ministry of Mechanical Engineering and Metallurgy and the Ministry of Mineral Resources, into a Ministry of Mechanical Engineering, and a Ministry of Metallurgy and Mineral Resources.

In 1977, Bulgaria participated in practically all of the major ongoing projects of the coordinated CMEA[4] plan for multilateral integration of undertakings through 1990.

In return for participation in the construction of the 500,000-ton-annual-capacity Kiyembay asbestos-dressing plant in Kazakhstan, U.S.S.R., Bulgaria is to receive some 40,000 tons of asbestos per year over a 12-year period. For participation in construction of the Mikhailov and Dnepropetrovsk ore-dressing plants in the U.S.S.R., Bulgaria is to receive 5.29 million tons of iron concentrate per year up to 1990. After completion of the Soviet Orenburg gas pipeline to the western frontier, which is to carry 28 billion cubic meters of natural gas per year westward, 15 billion cubic meters is earmarked as payment to the participants in the project. Bulgaria is to receive 2.8 billion cubic meters per year, a quantity

Digitized by Google

to be almost doubled after 1980. In addition, Bulgaria participated in construction of the 1.08-million-ton-annual-capacity Nikopolsk and Ermakovsk ferroalloy plants, as well as in the construction of the 750-kilovolts Vinnitsa-Albertirsa long-distance powerline (280 kilometers) linking the Ukraine with Hungary and supplying more power to the Mir (Peace) Grid.[5]

Dunaitrans, a Bulgarian-Soviet company for the joint operation of river vessels on the Danube, was established early in 1977. In the first year of its existence, the ships of Dunaitrans have transported some 6 million tons of freight between Bulgaria and the U.S.S.R.[6]

Government Policies and Programs.—Bulgaria's national income is expected to grow 6.8% and labor productivity 6.7% in 1978. Industrial output is to exceed last year's level by 7.7%. The State budget provides for an increase in capital investment during the year to L5,950 million. About two-thirds of the investment in production is allocated to the modernization and expansion of enterprises already in operation.

Output of the machine-building industry is to increase 13.7%, the chemical industry 11.1%, electric power about 10.5%, coal 11%, and steel 6.2%. The share of machine-building, the chemical industry, ferrous metallurgy, and power in foreign trade is to increase to 43.2% of the total volume of industry trade, compared with 41.3% in 1977.

PRODUCTION

Production of coal in Bulgaria, mainly lignite and brown coal, was 25.2 million tons in 1977. About 75% of this coal production was surface-mined and 25% deep-mined. The long-term plan, up to 1990, anticipates a 2.5-fold increase in production. Hard coal production will increase considerably after development, underway in 1977, of mines in the Dobrudja deposits. The year 1977 marked a new step in the expansion and modernization of the various copper and polymetallic mines and processing plants. Estimated mine output of copper (metal content) was about 57,000 tons in 1977, enough to meet national demand and to supply some exports of copper products. Production of copper is to rise at the end of the 5-year plan period (1976-80). Planned development of new deposits of copper include expansion of open pit mining from about 70% in 1977 to 80% to 85% in 1990. Bulgaria produced enough lead and zinc in 1977 to supply internal requirements and a modest export demand.

Crude steel production in 1977 amounted to 2.6 million tons, an increase of 5.2% over that of 1976. The share of electric furnace steel increased, while the share of open-hearth steel declined. Reconstruction of the steel plant at Pernik to a facility for production of quality steels continued in 1977. Expansion of the Kremikovtsi integrated iron and steel plant also continued in 1977. The main contractor for renovation of the Kremikovtsi plant was the Skoda-Plzen enterprise of Czechoslovakia.

Construction of the aluminum-rolling mill at Shuman continued in 1977. Production there is expected to be increased considerably by the end of 1980.

Bulgaria also mined small quantities of molybdenum and manganese. In 1977, natural gas was also produced in small quantities. Development plans, however, were based on a rapid increase in gas deliveries from the U.S.S.R. The small production of crude oil in Bulgaria in 1977 was of no practical significance since 90% of the national requirements came from the U.S.S.R.

Among nonmetals, Bulgaria continued to develop production of cement, fluorspar, kaolin and other clays, and building materials. Deposits of hard white and gray marble were discovered in the Kurdzhali District in southern Bulgaria. It was expected that 1978 exports of marble and slate are to show a threefold rise over 1977.

MINERAL FUELS AND RELATED MATERIALS —Continued			
Petroleum —Continued			
Refinery products —Continued			
Asphalt, including natural ____thousand 42-gallon barrels ____	2,120	2,385	2,977
Total ____do____	[r]73,792	75,774	78,077

[e]Estimate. [p]Preliminary. [r]Revised.

[1]In addition to the commodities listed, bismuth, chromite, gold, platinum, palladium, tellurium, uranium, barite, fluorspar, magnesite, and a variety of crude construction materials, such as common clays, gravel, sand, dimension stone, and crushed stone are produced, but information is inadequate to make reliable estimates of output levels.

TRADE

Bulgaria's total foreign trade was valued at more than L12 billion in 1977, an increase of 13% over that of 1976. CMEA member countries accounted for about 80% of Bulgaria's foreign trade, with the U.S.S.R. alone accounting for 55.6%. Bulgaria ranked third among the Soviet Union's trading partners in 1977. Bulgarian trade with developed market economy countries increased sharply from L743 million in 1970 to L1,500 million in 1977; the Federal Republic of Germany, Italy, France, and the United Kingdom were the principal trading partners.

In 1977, Bulgaria's balance of payments and trade with the nonsocialist countries improved substantially. The trend towards improving the export structure to include more manufactured goods and less raw materials continued in 1977. The share of machinery and equipment in the total volume of exports reached 45.5%, compared with 42% in 1976. Other important export commodities were chemicals (9%), products of ferrous metallurgy (5%), and some nonferrous metals and alloys. Imports comprised primarily machinery and equipment, fuels, mineral raw materials, and metals.[7] In 1977, Soviet deliveries to Bulgaria included 11.7 million tons of crude oil, 6 million tons of coal, 3 billion cubic meters of natural gas, 0.3 million tons of pig iron, 0.5 million tons of rolled steel, and 4.1 billion kilowatt-hours of electric energy.

In the current 5-year plan period (1976-80), 40% of all equipment received from the U.S.S.R. is to be used for the electric power industry, 24% for the chemical industry, and 21% for the ferrous and nonferrous industry. Soviet deliveries of crude oil, natural gas, coal, and metal ores and concentrates will continue to play an important role in the further development of Bulgaria's economy. In 1978, the trade turnover between Bulgaria and the Soviet Union is to increase by more than 11% compared with 1977, and is to reach 5.6 billion rubles annually.[8]

Bulgaria's main interest in U.S. products continues to be centered on technology and equipment for ferrous and nonferrous metallurgy and other industries.

COMMODITY REVIEW

METALS

Aluminum.—In 1977, construction continued on the Shuman complex, Bulgaria's first aluminum-processing complex, which is to have an annual capacity of 48,000 tons of rolled products. The raw materials for the new complex are to be supplied by the U.S.S.R. The aluminum-processing plant was designed in the Soviet Union and built with the assistance of Soviet specialists. Most of the machinery and equipment was from the U.S.S.R. In 1977, efforts were focused mainly on reaching the production capacity of the rolling mill and faster completion of the sheet, strip, and foil production shop scheduled to come onstream in 1979. Efforts were also concentrated on construction of the casting shop.[9] Construction of the aluminum complex was supervised by the Shuman Region Party Committee.

In 1975, Bulgaria and Yugoslavia signed a cooperative agreement that provided for a Bulgarian grant of long-term credit for expansion of the aluminum plant in Titograd, Yugoslavia. In return, Bulgaria is to receive 22,000 tons of aluminum ingots per year, as well as 3,000 tons of aluminum stock for which it will trade chemical and metal products over a 20-year period.

Copper.—In 1977, copper mine production (metal content) was estimated at 57,000 tons and production of electrolytic copper was estimated at 54,000 tons. Bulgarian copper requirements are supplied entirely by indigenous production.

The more important copper deposits are located in the Sredna Gora area near Panagyurishte, in the Chelopech and Elatsite region, and in the Burgas area near the Black Sea coast. In 1977, about 70% of total copper ore production came from the southern part of the Sredna Gora area where the 8-million-ton-annual-capacity Medet open pit mine is located. The balance came from the Chelopech underground mine, the Burgas, Panagyurishte, and other mines.

The Medet open pit mine and its ore-dressing plant began operations in 1964 and reached design capacity in 1972. Since then, the planned annual tonnage target was achieved each year.

During the past 6 years, however, the metal content of the ore has been below the expected level, and excavation was concentrated at the central part of the mine where the copper content was higher. As a result, the overburden removal plan was 95% fulfilled in 1974, 85% in 1975, 64.8% in 1976, and 61% in the first half of 1977. The accelerated deepening of the central area, without simultaneous enlargement of overburden removal, created instability leading to two large bench failures. In 1977, the lack of excavators, drills, dump trucks, and bulldozers, and a chronic shortage of spare parts for repairs at the Medet mine were among other problems reported.[10]

Medet has copper-molybdenum mineralization in granitic-monzonitic porphyry intrusions. The ore bodies consist of lenses and veins. The copper content of Medet's ore ranges from 0.05% to 0.6%. The main minerals are chalcopyrite, pyrite, and molybdenite. The Medet open pit mine uses a fully automated, computerized truck haulage control system.

The Chelopech mine (near Sofia) is Bulgaria's largest underground copper mine and has a capacity of 500,000 tons of ore per year. The development plan foresees the introduction of a high degree of mechanization and automation in the Chelopech mine and ore-dressing plant to increase capacity to 1.5 million tons per year.[11]

One of the largest projects in 1977 was the continuing development of an open pit copper mine at Elatsite, about 50 miles northeast of Sofia, that was begun in 1976. The mine has a design capacity of 10 million tons of ore per year. Estimated reserves at Elatsite are 250 million tons of copper ore. Recovery of the metal from the ore into concentrate is planned at 87%. Ore processing is to be computerized. Equipment for the Elatsite mine and dressing plant is to be imported from the Soviet Union.[12] By the end of 1979, when the complex is to come onstream, copper mining is to become an important branch of the economy in the Sofia region. The new technology applied to the development of the Elatsite mine is to reduce development lead time by 1 year and to eliminate 5 million cubic meters of overburden removal.[13]

The Dimiter Ganev copper fabricating plant, Bulgaria's sole enterprise that specializes in the production of nonferrous metal products, was reconstructed and expanded. In 1977, the plant was turning

Digitized by Google

out various copper products, copper alloys, and many other nonferrous products, some of which were exported to CMEA member countries, Iran, Iraq, Morocco, Italy, and Switzerland. In 1978, production of the Dimiter Ganev plant is expected to increase about 7.5% over that of 1977.[14]

Since completion of exploration of Medet and Elatsite, another new copper deposit, Assarel, was discovered and explored. Plans include further exploration of Assarel and other new copper deposits in the Panagyurishte region.[15]

The Institute of Ore Mining and Dressing in Sofia is planning the development of a surface mine and an ore-dressing plant for a copper deposit in Vietnam using Bulgarian equipment. Bulgaria is also planning the development of a similar project in Algeria.

Iron and Steel.—Production of iron ore in Bulgaria was estimated at 2.3 million tons in 1977. Principal iron ore deposits are located at Kremikovtsi, north of Sofia, and contain relatively low-grade ores. The ore basically represents limonite (70%), siderite (18%), and hematite (12%). Iron ore is surface mined, and estimated reserves are placed at 250 million tons of ore. The Kremikovtsi iron ore also contains a number of other components (barite, lead, manganese, and others). Bulgarian imports of iron ore and concentrates amounted to 1.7 million tons in 1977, most of it from the U.S.S.R.

In 1977, production of pig iron totaled 1.6 million tons, an increase of 3.6% over that of 1976. About 311,500 tons of pig iron was imported in 1977. Crude steel production was 2.6 million tons, an increase of 5% over the level of 1976. Production of rolled steel in 1977 was 2.9 million tons, an increase of about 6% over that of 1976. Rolled steel imports in 1977 totaled 1.1 million tons and exports totaled 1.0 million tons.

Steel product imports are significant because the country, as yet, has been unable to produce the variety of rolled steel products required. Domestic production accounted for 97% of apparent rolled steel consumption in 1977.

In 1977, oxygen-converter steel accounted for about 57.2% of the steel output in Bulgaria, maintaining its share at approximately the same proportion as in 1976. Output of the open-hearth process declined, accounting for about 18.8%, and that by the electric-furnace process increased to 24%.

In 1977, reconstruction of the Kremikovtsi integrated iron and steel plant was in progress; the redesigned production lines at rolling mills are to bring the capacity of the plant up to 3.2 million tons per year.

The Lenin metallurgical plant, which was also under reconstruction in 1977, is to reach a capacity of up to 900,000 tons of rolled products per year.[16]

Lead and Zinc.—Lead-zinc ore production in Bulgaria has been about 6 million tons per year in recent years. In 1977, production of primary lead in Bulgaria was estimated at 117,000 tons and production of zinc was estimated at 87,000 tons. Bulgaria has several lead-zinc mining enterprises: Gorubso, Ustreme, Madjarovo, Ossogovo, Dimitrov, and a few others. In 1977, Gorubso continued to be the leading lead and zinc producer with estimated output of over 3 million tons of ore.

The principal mining centers of Gorubso enterprise are Madan, Rudozem, Leku, Kerdzhaly, and Zlatograd. These centers have many mines and beneficiation plants. Lead-zinc deposits in Bulgaria are principally of hydrothermal origin. The deposits are veined or stratified masses, usually containing galena, sphalerite and secondary silver, cadmium, bismuth, and other components. All lead-zinc ores are mined by underground methods.

In 1977, the U.S.S.R. and Bulgaria continued the joint development of nonferrous mining and metallurgy. During the 1976-80 period, L19.5 million are planned to be allocated in Gorubso lead-zinc enterprises for renovation and reconstruction of mines and processing plants.[17]

NONMETALS

Cement.—Bulgarian cement production for 1977 was 4.7 million tons, a 7% increase over that of 1976. Cement production in 1978 is to increase by about 1 million tons to 5.7 million tons. A new line with a capacity of 600,000 tons per year at Temelkovo is expected to start production in 1979.[18] Temelkovo and another large cement plant at Devnya are being built and equipped with Soviet assistance.

Fertilizer Materials.—Production of nitrogenous fertilizer in 1977 was 407,802 tons (in terms of nutrient content), an increase of 9.7% over that of 1976. Phosphatic fertilizer production reached 278,472 tons (P_2O_5 content), an increase of 15.3% over that of 1976. Bulgaria is self-sufficient in nitrogenous fertilizers and exported 283,000 tons (nutrient content) in 1977. The 1977 imports of

Digitized by Google

phosphatic fertilizers and phosphate rock were 31,000 tons (P_2O_5 content) and 954,000 tons, respectively. Imports of potassium fertilizers increased from 50,000 tons (K_2O content) in 1976 to 58,000 tons in 1977.

Bulgaria is expanding its chemical plants. Productive capacity for ammonia, urea, and nitrogenous and phosphatic fertilizers is to increase 80% during the 1976-80 period, compared with 1971-75.

Development plans foresee the following production of fertilizers in 1980: Ammonia, 1.5 million tons; nitrogenous fertilizers, 716,000 tons; urea, 500,000 tons; and phosphatic fertilizers, 450,000 tons. Fertilizer production in Bulgaria is centered at Devnya, Dimitrovgrad, Stara Zagora, Varna, and Vratsa.

The Devnya complex, situated near Varna, has four production units specializing in many products that include fertilizers. The plant for mineral fertilizers, put into operation in 1974, produces complex fertilizers containing nitrogen, phosphorus, and potassium as well as triple superphosphate. Natural gas is used as raw material for nitrogenous fertilizers, and apatite and phosphorite are used for phosphatic fertilizers (raw materials are imported from the U.S.S.R. and elsewhere).[19] Reportedly, total fertilizer production at Devnya was about 1.2 million tons in 1977.

The Dimitrovgrad complex produces superphosphates and nitrogenous fertilizers. A new ammonia plant with an annual capacity of 450,000 tons is planned to come into production in 1978. A new 280,000-ton-annual-capacity ammonium sulfate plant was also under construction at Varna. Two new production facilities are to be built at Vratsa; a 200,000-ton-per-year urea plant and a 146,000-ton-per-year ammonia unit.

MINERAL FUELS

Total primary energy production derived from fossil fuels, hydroelectric, and nuclear power generation in Bulgaria was 15.0 million tons of standard coal equivalent (SCE) in 1977, compared with 14.7 million tons in 1976.

In 1977, the share of coal (lignite, brown, and bituminous) in total primary energy production was 90%; petroleum, 1.3%; natural gas, 0.7%; hydroelectricity, 2.7%; and nuclear power, 5.3%. The total consumption of primary energy increased from 41.9 million tons of SCE in 1976 to 42.6 million tons in 1977. In 1977, coal provided about 47.2% of total consumption; petroleum, 41.1%; natural gas, 8%; hydroelectric energy, 0.9%; nuclear power, 1.9%; and net imports of energy, 0.9%. To meet fuel requirements, Bulgaria imported 65% of the primary energy consumption in 1977.

Total primary energy balances of Bulgaria for 1976-77 are shown in table 4.

In 1977, 29.7 billion kilowatt-hours of electric energy was produced in Bulgaria, an increase of 7% over that of 1976. The Kozloduy nuclear powerplant (880 megawatts) produced about 6 billion kilowatt-hours, accounting for about 20% of the national output in 1977. It is expected that after 1980, half of the electric power produced in Bulgaria will come from nuclear plants.

Table 4.—Bulgaria: Total primary energy balance for 1976 and 1977

(Million tons of standard coal equivalent[1])

	Total primary energy	Coal (lignite, brown, bituminous) and coke	Petroleum and refinery products	Natural gas	Hydroelectric energy	Nuclear energy	Other
1976:							
Production	14.7	13.4	0.2	0.1	0.4	0.6	--
Imports	27.3	6.5	17.4	2.9	--	--	0.5
Exports	.1	--	--	--	--	--	.1
Apparent consumption	41.9	19.9	17.6	3.0	.4	.6	.4
1977:							
Production	15.0	13.5	.2	.1	.4	.8	--
Imports	27.7	6.6	17.3	3.3	--	--	.5
Exports	.1	--	--	--	--	--	.1
Apparent consumption	42.6	20.1	17.5	3.4	.4	.8	.4

[1]1 ton standard coal equivalent (SCE) = 7,000,000 kilocalories. Conversion factors used are: Bituminous, 1.0; lignite and brown coal, 0.5; crude oil, 1.47; petroleum products, 1.54; natural gas (per thousand cubic meters), 1.33; hydroelectric and nuclear energy (per thousand kilowatt-hours), 0.125.

Digitized by Google

Coal.—Production of coal and lignite in 1977 was 25.2 million tons, a decrease of 1.2% from that of 1976.[20] Included in this amount were 24.9 million tons of lignite and brown coal, and 288,000 tons of bituminous and anthracite. Total coal production in 1978 is planned to reach 29.3 million tons. The plan for long-range development provides for a coal production of 27 to 28 million tons in 1980, about 46 million tons in 1985, and 56 million tons in 1990. Major anticipated changes will feature an increase in preduction of lignite, a decline in output of brown coal, and a substantial increase in production of bituminous coal after development of mines at the Dobrudja deposits.

In 1977, bituminous coal imports amounted to 2.7 million tons and imports of anthracite, about 3.5 million tons, almost all from the U.S.S.R. and Poland. Imports of coke amounted to 359,000 tons, all from the U.S.S.R.

Lignite production in Bulgaria is centered in the Maritsa-East basin and brown coal production in the Bobov Dol, Pernik, and Pirin basins. In 1977, the Maritsa-East basin surface-mined output accounted for about 58% of the total coal production in Bulgaria.[21] Reserves at Maritsa-East lignite basin are estimated at 2.9 billion tons. The lignite ranges in calorific value from 1,200 to 1,600 kilocalories per kilogram (2,200 to 2,900 Btu per pound). Development plans include the creation of a giant Maritsa-East complex that is to produce 46 million tons of coal annually by 1987. In 1990, Maritsa-East basin is expected to produce 69% of the total coal production in Bulgaria. Up to 1987-90, several new coal mines are to be put into operation in this basin.

In 1977, the first of Maritsa-East's three 210-megawatt electric power stations was put into operation, and another is to be operating by the end of 1978. The Maritsa-East complex produces the cheapest coal-fired electric power in Bulgaria. The complex consists of three operating surface mines, Troyanovo 1, 2, and 3.[22] Troyanovo 4, with a projected capacity of 6 million tons per year, is to be developed during 1976-80 and is to start production after 1981.[23] Lignite mining at Maritsa-East is highly mechanized. The mine transport system is fully mechanized and features extensive use of conveyor belts. An agreement was signed with the German Democratic Republic to supply installations for the complete mechanization of all mining at the Maritsa-East coal basin by 1982.

Brown coal and bituminous coal production in Bulgaria are still below national requirements. The 1976-80 plan calls for expansion of the Bobov Dol brown coal mine to supply the region's electric powerplants but development lagged at the new Bobino mine in that basin. The plan for 1978 calls for 2.8 million tons of brown coal production in the Bobov Dol basin.

Recently, deposits of bituminous coal have been discovered in Dobrudja but their development will start in the coming 5-year plan period (1981-85).[24] In the Dobrudja basin, coal reserves are estimated at 1.2 billion tons and are reported to have a calorific value of 7,500 to 8,000 kilocalories per kilogram. The coal beds lie at depths below 1,300 meters and are overlain by water-bearing formations.

Natural Gas.—Extraction of natural gas in Bulgaria decreased from 474 million cubic meters in 1970 to 37.2 million cubic meters in 1976. Imports of natural gas from the U.S.S.R. were about 2,500 million cubic meters in 1977.

Bulgaria's gas production comes mainly from the Chiren gasfields in the northwest. Bulgaria started receiving gas through the U.S.S.R.-Bulgaria pipeline in 1974. In 1977, 20 enterprises were receiving gas from this pipeline. The Lenin metallurgical plant at Pernik and other plants were to be connected to this gasline next. Construction of the southern branch of the trunk pipeline and expansion of gas distribution stations continued in 1977.[25] Plans were to complete the south branch in 1980. Bulgaria is to receive 2.8 billion cubic meters of gas per year from the Orenburg pipeline, starting in the fourth quarter of 1978.

Petroleum.—Crude oil production is relatively small in Bulgaria. In 1977, indigenous production of crude oil was estimated at 129,000 tons. Bulgaria's oil comes from the small oilfields in the northwestern part of the country.

In 1977, 11.7 million tons of crude oil was imported from the U.S.S.R. Additional crude oil supplies came from Iraq, Iran, and Libya.[26] Imports of crude oil in 1977 increased 8.3% compared with 1976. In 1980, imports of crude oil are expected to reach 16 million tons.

Oil comes into Bulgaria by tanker across the Black Sea. Bulgaria's total crude oil processing capacity of 15.5 million tons per year is distributed as follows: About 12 million tons at Burgas, 1 million tons at Pleven, and 2.5 million tons at Ruse. The

Digitized by Google

Burgas petrochemical plant is the main producer of fuel oil in Bulgaria. In 1977, Burgas processed an additional 1.2 million tons of petroleum. The value of refined petroleum products produced in 1977 was about L40 million higher than in 1976.[27] The construction of a new oil refinery at Burgas was underway in 1977.[28]

On September 29, 1977, Bulgaria's Minister of the Chemical Industry and the Minister of Petroleum Refining and Petrochemical Industry of the U.S.S.R. signed a general agreement on specialization and production-sharing in petrochemicals until 1990. Extensive prospecting in Bulgaria for new oilfields, including offshore exploration in the Black Sea, will be continued in 1978-80. In January 1978, it was reported that Bulgaria will expand its participation in oil and natural gas projects in the U.S.S.R. and will be compensated for its participation by deliveries of oil and natural gas.

In 1977, the second section of the Burgas-Sofia oil trunk pipeline was commissioned. This pipeline will carry 80% of the diesel fuel that was transported previously by tankcars.

Transportation of oil to the more remote regions in northwestern and northeastern Bulgaria has been more efficient and the average distance of tankcar travel has been reduced by about 400 kilometers from a terminus in Sofia. Fuel oil could be also distributed from intermediate stations on the pipeline to the other parts of the country. The pipeline was to carry 2 million cubic meters of oil products during 1977.[29]

[1]Foreign mineral specialist, Branch of Foreign Data.

[2]Because of fluctuating exchange rates, a meaningful conversion to U.S. currency is impractical. Therefore, values are reported in Bulgarian leva (L) and are not converted. The official exchange rate in June 1977 was L1=US$1.05=0.78 Soviet rubles.

The Mineral Industry of Burma

By Gordon L. Kinney[1]

The gross domestic product (GDP) of Burma for 1977[2] was estimated at just over $4.0 billion[3] at current prices. Revised GDP figures for 1975-76 were $3,510 million for 1975 and $3,996 million for 1976. The GDP at constant 1969 prices was $1,839 million in 1976 and estimated at $1,842 million in 1977. One encouraging sign was the taming of the chronically high inflation rate. The revised Rangoon consumer price index (1972=100) increased about 14% during the year to 256, a smaller increase than in previous years. The balance-of-payments deficit was again held to a very manageable level—$29 million (revised) in 1976 and $22 million in 1977. Exports totaled an estimated $240 million, and imports increased to an estimated $312 million during 1977.

The latest figures show that the population increased 2.2% in 1977 to 31.5 million. The total active labor force was 12.4 million, with 66,000, or 0.53%, engaged in mining activities. These miners produced about 1.7% of the net 1977 output of goods and services.

The value of the output of the mineral sector for 1976 was $69 million at current prices, a 31% increase over the 1975 figure.[4] Value figures for 1977 were not available but will probably be between the 1975 and 1976 levels at constant prices and could show a modest increase at current prices.

The overall physical output of mineral products during 1977 was only slightly greater than in 1976, but the long-term trend is one of gradual decline, primarily owing to lack of new investment and failure to bring any significant new mines into production. Although its current output is small, Burma was a mineral producer of some consequence before World War II and still is considered to have a good potential for expansion. At present, however, no foreign investment is allowed in mining. All important mining operations are conducted by the Government-owned mining corporations. Foreign participation has been limited to technical assistance and financial aid. Small-scale, family-operated mines are still privately owned, with most of the output being sold to the Government.

The major aim of the Government's mining policy at present is to modernize or reopen existing mines that were in production before World War II but are now operating at reduced production levels or have closed because of deteriorated equipment and/or a lack of investment capital.

Despite Burma's favorable mineral potential, many of the most promising areas for exploration have not been mapped or prospected in any detail because of security problems.

One bright note in the mineral industry was the continued growth of the small petroleum sector during the year. The Government continued its program to upgrade the petroleum transportation system, and these improvements were instrumental in allowing a substantial increase in domestic crude oil production. In the past few years, refinery output has been restricted mainly by outmoded transport facilities rather than by a lack of crude oil at the oilfields. The Government continued its firm policy against petroleum imports, and shortages were encountered again but to a much lesser extent than in 1976. The refineries operated essentially at capacity during 1977, and the fuel shortages are expected to continue until completion of the new Japanese-financed refinery in 1981. Fourteen new development wells were sunk at existing fields during 1977. The use of im-

Digitized by Google

proved secondary recovery techniques and these new wells contributed to the production increase in 1977. Production should continue to climb during 1978 as the full impact of the new wells, techniques, and transport improvements is felt.

PRODUCTION

Burma's total 1977 mineral output increased slightly over that of 1976. Although gains were registered in some minerals, the overall picture was one of declining output when viewed against average production figures of the past 5 years. Only coal, antimony ore, and tungsten concentrates reflect a rising trend. For all other metallic ores, on which data are available, the output trend has been declining.

Industrial minerals again had a mixed year; feldspar, gypsum, and dolomite showed sizable drops in production, and barite, yellow ocher, and limestone recorded substantial increases.

Crude oil production rose for the fourth straight year, showing a 28% increase over that of 1976. Natural gas production, which has nearly doubled since 1974, continued climbing steadily.

The value of the production of individual minerals for 1977 was not available from official sources, making comparisons and conclusions difficult and often subject to later change. A Burmese Government report[5] stated that the value of overall mineral production for 1976 (provisional) at constant 1969 prices increased 31%. The 1977 increase, however, may be significantly less.

[e]Estimate. [p]Preliminary. [r]Revised. NA Not available.

[1]In addition to the commodities listed, Burma also produces pottery clay, common sand and gravel, other varities of crude construction stone, and other varities of gem stones, but available information is inadequate to make reliable estimates of output levels.

[2]Data are for fiscal year beginning Apr. 1 of that stated.

[3]Includes fire clay powder.

[4]Revised to none.

TRADE

The mining industry usually ranks third, after agriculture and forestry products, in value of exports. Exact figures are not available at this writing, but the relative importance of the mining sector is not believed to have changed in 1977. Foreign exchange revenue for minerals constituted about 7% of Burma's total receipts. Burma normally exports all of its mineral output, particularly in the metallic sector. Most ores are exported in unprocessed form because there are no substantial smelting or refining facilities in the country except the old lead and zinc smelter associated with the Bawdwin mining operation.

COMMODITY REVIEW

METALS

Antimony.—Production continued to climb; antimony being one of the few minerals to show a sustained growth pattern over the last few years. Production has increased an average of 17% per year since 1973. Growth could continue for many years as geologic exploration programs underway outline the actual reserves available. At present, most antimony mines are small-scale, labor-intensive operations at rich surface outcroppings. Antimony ore is sold by individual miners to the Government's Mineral Development Corp.

Copper.—Delineation drilling of the Monywa copper deposits continued under United Nations Development Program (UNDP) auspices during 1977. No additional reserves data were released. The previously reported figures of over 60 million tons of 0.7%+ copper ore indicated that an open pit mine and processing facilities would be feasible, but little development work was underway at yearend. Apparently, the reported pilot plant was not yet operating at the deposits. The proposed West German and additional Japanese bilateral assistance for the project did not materialize. There were reports of possible Yugoslav assistance, but no details were available. This copper ore site has the attraction of being located in a secure zone and being close to the rail and river transportation system. The Government was reportedly anxious for its development to begin.[6] The plans call for an 8,000-ton-per-day mill and mining operation and a 20,000-ton-per-year smelter.

Lead and Zinc.—Production of lead and zinc concentrate increased 37% and 34%, respectively, over the 1976 figures. However, tonnages produced in 1977 were still well behind the average for the previous 5-year averages. The Ministry of Planning and Finance Report to the Legislature[7] indicated that lead and zinc exploration drilling was conducted during the year, apparently at an increased level, but no results were published. Most of the lead and zinc production continued to come from the famed Bawdwin mine in Northern Shan State, which was once one of the richest lead deposits in the world. Today production is hindered by declining ore grade and the deteriorating mine and plant facilities, and although several plans to modernize the mining and smelting complex with foreign assistance have been advanced, little investment has actually been made. The West German Government extended a 6-million-Deutsche-mark (DM) loan for equipment modernization. The major deterrent to large-scale investment is the location of the mine in an area that is increasingly threatened by armed insurgent forces. The situation also prevents further exploration of nearby areas believed to have additional rich deposits. As yet, work has not started on the new West German-financed DM50-million zinc smelter to be constructed at Pyinmana 19°44' N, 96°13' E near Eala 19°37' N, 96°13' E. This would be fed mainly from the Bawdwin mine's slag and tailings piles. For many years, the zinc content was not exploited, and the waste piles have been accumulating since 1905.

Tin and Tungsten.—Production of tin and tungsten concentrates increased considerably during 1977 after a rather poor showing in 1976. Although output returned to the level of the past 5-year average, it was still only about 10% of the pre-World War II level.[8] The potentially rich deposits along the Tennassarim coast continued to be underexploited owing to a lack of capital investment, the presence of armed insurgents, and a lack of firm Government control in the area. At present, about 75% of production comes from small-scale private mining operations which sell their production to the State. The unstable conditions permit considerable illicit tin and tungsten mining, with the output often being smuggled out of Burma through Thailand and Malaysia. Since 1975, a United Nations sponsored offshore tin exploration survey has been underway along the Tennassarim coast. Recently, a sophisticated ore-sampling drill was brought in from Singapore on a specially constructed barge. It was reported that the potential offshore mining was less likely to encounter security problems.

Modernization of the old Heinda Mine, being done with West German aid, was completed in March 1977, and the mine was reported to be operating at yearend with West German technical advisers on the scene. The mine was designed to produce about 1,000 tons of tin concentrate per year. Exploration work was underway at the nearby Hermyingy underground mine, but no significant ore production was reported.

In March 1977, the World Bank's International Development Association approved a $16 million loan to cover foreign exchange costs of developing the tin and tungsten alluvial deposits in the Heinze Basin, 280 kilometers southeast of Rangoon. Work is to include a new dredge and related facilities and a new tin and tungsten concentrating

Digitized by Google

plant at Tavoy (14°05' N, 98°12' E). Work on the project was underway at yearend. Proved ore reserves were reported to be 32 million cubic meters of sand containing about 5,000 tons of tin.

NONMETALS

There was little new development in the industrial minerals sector in 1977. Limestone, barite, and some types of clays production increased, while feldspar declined. Limestone production rose 80% to over 1 million tons. Most of this was consumed in the manufacture of 269,000 tons of portland cement. This was the second consecutive significant annual increase in cement production. First-quarter-1977 statistics indicated a significant upward trend in brick and tile production also. A Chinese source[9] reported completion of a Kyangin cement plant, but other details were not available.

Negotiations were successfully completed in January 1977 with Asahi Glass Co. Ltd., of Japan for a sheet glass plant and production technology. The plant will be located in Bassein (16°47' N, 94°44' E) and will use locally obtained glass sands. Reported capacity of the plant will be 12,000 tons per year. The existing Syriam glassware factory planned to increase its present output by replacing two old 25-ton-per-day furnaces with two new furnaces capable of producing 50 tons per day.

MINERAL FUELS

Coal.—Burma continued to have a fuel shortage during the year. The country has few known deposits of coal, and little information was available on any plans to increase the presently trivial coal production. The main producers were still believed to be the Kalewa and Nama coal mines. Production increased in 1977 to over 23,000 tons, continuing the slow but steady increase of the last few years. There were no available data on 1977 coal imports.

Petroleum and Natural Gas.—Petroleum production was the bright spot in Burma's mineral industry. Approximately 10.4 million barrels of crude oil was produced during the year, a 27% increase over the 8.2 million barrels (revised) reported for 1976. That level of production was just about the limit of the refining capacity of Burma's two small refineries, and corresponded in tonnage to about 2% of Indonesia's oil output. Demand, however, continued to climb along with production. The Burmese Government continued its policy of no petroleum imports, and shortages continued to plague the industry, albeit on a much reduced scale for 1977. The well count and crude oil production in U.S. barrels by field for 1977, together with the 1975 and 1976 totals, are summarized in the following tabulation:

Field	Number of wells				Average yearend production (42-gallon barrels per day)
	Flowing	Pumping	Gas-lift	Total	
Mann	96	6	--	102	20,400
Yenanguang	3	151	4	158	3,600
Myanaung	13	34	4	51	2,950
Chauk	4	97	--	101	1,300
Prome	16	15	--	31	1,300
Letpando	4	--	--	4	800
Total	136	303	8	447	30,350
1976	115	261	8	379	24,994
1975	105	361	--	466	16,559

Natural gas production was 9.6 billion cubic feet (272 million cubic meters) in 1977 versus 8.5 billion cubic feet (241 million cubic meters) in 1976. Output was used in industry and in gas turbine electricity generating plants.

There was no offshore exploration activity in Burma in 1977. The four foreign operators that signed service contracts in 1974—Esso Co.; Martaban-Cities Service, Ind.; Japanese Arakan Oil Development Corp., and France's CFP (Total)—all let their offshore licenses expire following unsuccessful drilling through October 1976 within their respective concessions. Of the 17 holes drilled offshore by the four companies, none yielded commercial quantities of oil and 1 produced a small amount of natural gas. The anticipated reopening of bidding for new concessions did not take place during 1977 but may occur in the near future.

Onshore exploration and development have been exclusively by the Government's

Digitized by Google

Myanma Oil Corp. (MOC), with no foreign firms being invited to participate. MOC conducted somewhat less exploration activity in 1977 than in previous years. The major areas of interest were the upper Chindwin Basin and the Irrawaddy Delta. A number of test wells were drilled in these areas and also in the area between Prome and the Mann oilfield. There were no reports of significant finds in 1977.

Twenty-four new development wells were sunk at existing fields during the year. Of these, 17 were at Mann oilfield, 4 at Letpando, and 3 at Yenangyaung. These new development wells and improved secondary recovery techniques accounted for the year's production increases.

In the refining sector, contracts for construction of the new 25,000-barrel-per-day refinery at the Mann oilfield were finally signed in December 1977. The signing came nearly a year after the announcement of the loan agreement between the Japan Overseas Economic Cooperation Fund and the Burmese Government. Japan's Mitsubishi Heavy Industries Ltd. will be the major contractor for the full turnkey contract, which is to be completed in 1981. The objective of the plant is to supplement Burma's needs for petroleum products and to produce raw materials for synthetic fibers and petrochemicals. The range of products will be motor fuels through JP-5. The cost, reported at Japanese yen at 29.95 billion, equates to well over $100 million depending on the exchange rate used. The remote location of the refinery in central Burma added considerably to the cost. The increased refining capacity will meet Burma's projected petroleum products needs for several years.

The crude oil transportation bottlenecks encountered in the last few years have received priority attention by the Government, and the overall situation was greatly improved by yearend 1977. The most important development was the completion of the 218-kilometer-long, 25.4-centimeters-in-diameter pipeline from the Mann oilfield to the Gwema loading point at Prome. In addition, work was begun in 1977 on a project to extend the Mann pipeline the remaining 280 kilometers directly into the Syriam refinery near Rangoon. The line is being financed by a loan from the Chase Manhattan Bank and should be finished by early 1979. Completion of the line will eliminate the slow and costly river barge transport presently used to deliver most of the crude oil to the refinery.

The Mineral Industry of Canada[1]

By Walter C. Woodmansee[2]

The Canadian nonfuel mineral industry continued its gradual, sporadic recovery from the recession that prevailed during 1974-75. Prices were higher and demand was improved for some minerals but remained weak for others. Among those mineral commodities evidencing improved markets were aluminum, rolled steel, molybdenum, lead, gold, silver, and potash. Production was curtailed in several sectors of the industry. Employment was down, and some labor layoffs were necessary. The financial positions of some companies were impaired by low production, large inventory carrying charges, and rising costs.[3]

In the fuel sector, prices and markets for oil and gas, coal, and uranium remained strong. Exploration activity was intensive, particularly for natural gas and uranium.

PRODUCTION

According to preliminary estimates of the Department of Energy, Mines and Resources and Statistics Canada, the total value of mineral raw materials production reached $17.1 billion[4 5] in 1977, compared with $14.5 billion in 1976, making it the 20th consecutive year that the total mineral output value has continued an upward trend. This production was 9% of the gross national product (GNP) estimated at $197.5 billion for the year. Mineral fuels, principally crude oil and natural gas, accounted for $9.4 billion; metals, $5.3 billion; and nonmetals, including construction materials, $2.4 billion. The oil and gas industry alone accounted for 51% of the total mineral output value for the year. The most important nonfuel mineral products in terms of value were iron ore, nickel, copper, zinc, asbestos, potash, and cement.

Value of mineral output increased in each of the 10 provinces and the Yukon and Northwest Territories. The Province of Alberta was the leader by far because of its oil and gas output. Production values of the provinces and territories follow:

Province or territory	Value, billions
Alberta	$8.0
Ontario	2.5
British Columbia	1.8
Quebec	1.5
Saskatchewan	1.0
Newfoundland-Labrador	.8
Manitoba	.5
New Brunswick	.3
Northwest Territories	.3
Nova Scotia	.2
Yukon Territory	.2
Prince Edward Island	(1)
Total	17.1

[1]Less than 1/2 unit.

In 1977, Canada ranked first in world production of mine nickel and mine zinc; second in output of molybdenum, uranium, asbestos, potash, and elemental sulfur; third in output of gold, platinum-group metals, silver, titanium concentrate, and gypsum; fourth in output of primary aluminum, mine copper, and mine lead; and fifth in output of iron ore.

In January, there were 335 nonfuel mining operations throughout the country. In

Digitized by Google

metal mining, there were 107 underground mines, 39 open pits, 8 combination underground and open pit operations, 1 surface tailings operation, and 53 placer gold operations. In nonmetal mining, including construction materials, there were 18 underground mines, 102 open pits, and 7 solution-mining operations. There were 17 mine closures and no newly productive mines during the year.

TRADE

In 1977, exports of crude and fabricated mineral products totaled $12.3 billion, 31% of total exports of $40 billion. About 69% of these exports went to U.S. markets and 13% went to members of the European Economic Community (EEC), principally the United Kingdom.

Imports of crude and fabricated mineral products totaled $4.4 billion, 18% of total imports valued at $24 billion. Crude petroleum accounted for $3.1 billion or 70% of mineral imports. Principal sources of oil were Venezuela and Saudi Arabia. Imports of coal, valued at $589 million, were from the United States. Other major mineral imports were bauxite, alumina, and aluminum scrap ($178 million) and iron ore and iron and steel scrap ($107 million).

Table 3.—Canada: Exports and reexports of mineral commodities

(Metric tons unless otherwise specified)

Commodity	1975	1976	Principal destinations, 1976
METALS			
Aluminum:			
Alumina (excluding abrasive grades), metal content	23,986	15,944	United States 13,161; United Kingdom 1,125.
Metal:			
Scrap	42,832	51,526	United States 41,179; Japan 6,385.
Unwrought	510,354	507,967	United States 356,103; People's Republic of China 22,894.
Semimanufactures[1]	25,074	29,304	United States 11,888; Venezuela 8,771; Pakistan 3,899.
Cadmium	643	1,555	United States 1,057; United Kingdom 382.
Calcium	310	286	Mainly to United States.
Cobalt:			
Metal	659	1,039	Do.
Oxides and salts, gross weight	561	471	United Kingdom 461; Japan 10.
Columbium concentrate[2] kilograms	9,500	5,033	All to United States.
Copper:			
Ore and matte, metal content	314,518	294,714	Japan 207,655; United States 47,656.
Slag, skimmings, and sludge, metal content	102	6,831	West Germany 3,599; Belgium-Luxembourg 2,899.
Metal:			
Scrap:			
Unalloyed	16,475	16,464	United States 9,898; Republic of Korea 1,935.
Copper alloys	13,769	16,768	United States 11,467; Japan 1,493.
Unwrought, unalloyed	319,716	306,130	United Kingdom 92,854; United States 86,625.
Semimanufactures:			
Unalloyed	26,600	28,606	United States 11,520; Venezuela 3,159.
Copper alloys	8,758	11,050	Mainly to United States.
Gold:			
Ore and concentrate, metal content thousand troy ounces	210	184	Japan 92; United States 83.
Metal:			
Unalloyed do.	NA	1,787	United States 1,435; Mexico 263.
Alloyed do.	NA	67	United States 43; Trinidad and Tobago 13; Jamaica 8.
Iron and steel:			
Iron ore thousand tons	36,034	44,685	United States 24,500; Japan 5,088.
Metal:			
Scrap do.	420	1,027	United States 715.
Pig iron and related materials do.	441	385,175	United States 236,646; Netherlands 87,245.
Ferroalloys:			
Ferromanganese	1,240	9,861	Mainly to United States.
Ferrosilicon	29,101	34,709	United States 30,045.
Other	2,024	7,320	United States 6,555.
Steel ingots and other primary forms	35,499	130,149	United States 80,756; Italy 27,274.
Semimanufactures:			
Bars, rods, angles, shapes, sections	226,462	357,143	United States 246,380.
Universals, plates, sheets, strip	508,938	804,650	United States 464,525.
Rails and accessories	128,404	186,195	United States 75,874.
Wire	44,315	46,409	Mainly to United States.
Tubes, pipes, fittings	333,581	284,281	Do.
Castings and forgings, rough	157,367	214,880	Do.
Lead:			
Ore and concentrate, metal content	211,909	140,942	Japan 75,122; United States 27,909.
Metal:			
Scrap, including alloy scrap	12,117	14,910	Republic of South Africa 6,843; West Germany 3,787.
Unwrought, unalloyed	109,965	114,570	United States 38,486; United Kingdom 37,016.
Semimanufactures	6,067	4,493	Mainly to United States.
Magnesium metal	4,733	3,445	United Kingdom 1,171; United States 673.
Mercury 76-pound flasks	[3]12,891	44,415	Italy 13,172; Algeria 10,248; Yugoslavia 6,739.
Molybdenum ore and concentrate, metal content[3]	15,680	14,553	Japan 4,865.
Nickel:			
Ore, matte, and speiss, metal content	84,391	72,688	United Kingdom 37,232; Norway 26,893.
Oxide, metal content	38,527	47,957	United States 28,683.
Metal:			
Scrap	3,232	2,599	United States 1,557.
Unwrought	99,948	99,394	United States 75,269.
Semimanufactures	10,431	12,224	United States 9,952.

Table 3.—Canada: Exports and reexports of mineral commodities —Continued

(Metric tons unless otherwise specified)

Commodity	1975	1976	Principal destinations, 1976
METALS —Continued			
Platinum-group metals:			
Concentrates, residues, and mattes, metal content troy ounces	433,109	388,105	Mainly to United Kingdom.
Metals:			
Scrap do	21,403	31,359	United States 20,487.
Other do	83,548	65,544	United States 32,806; United Kingdom 23,817.
Selenium metal and salts, metal content kilograms	238,680	246,345	United States 144,877.
Silver:			
Ore and concentrate, metal content thousand troy ounces	15,156	14,011	United States 8,757; Japan 3,113.
Metal, refined do	24,235	30,914	Mainly to United States.
Tin ore and concentrate, metal content[3]	1,052	796	United Kingdom 499.
Titanium:[2]			
Ilmenite and ilmenite sand[4]	200	185,631	All to Australia.
Titanium slag (70% TiO_2)	192,915	184,183	All to Canada.
Uranium and thorium concentrates value, thousands	$46,256	$93,939	United States $73,105.
Zinc:			
Ore and concentrate, metal content	705,144	653,370	Belgium-Luxembourg 229,700; Japan 117,628; West Germany 111,624.
Metal:			
Scrap, dross, ash, blue powder	18,376	19,938	United States 14,213; United Kingdom 2,012.
Unwrought	247,280	352,071	United States 274,448; United Kingdom 41,809.
Semimanufactures	r1,773	4,536	Mainly to United States.
Other:			
Ores and concentrates, gross weight	254,714	300,495	Japan 94,008; West Germany 68,419; United States 58,279.
Ash and residue containing nonferrous metals	13,568	294	United States 223.
Oxides, hydroxides, and peroxides of metals	59,134	79,207	Mainly to United States.
Metals:			
Base metals including alloys, all forms	1,339	754	United States 523.
Precious metals[5] troy ounces	58,655	47,243	Cuba 40,255.
NONMETALS			
Abrasives:			
Natural	222	25	Mainly to United States.
Fused alumina, crude and grains	127,455	154,002	Do.
Silicon carbide, crude and grains	78,824	86,460	Do.
Grinding and polishing wheels and stones value, thousands	$1,020	$883	United States $786.
Asbestos:			
Crude	183	83	United Kingdom 48.
Milled fiber, all grades thousand tons	1,074	1,651	United States 613; West Germany 150.
Barite, crude	45,606	60,296	Mainly to United States.
Cement, portland thousand tons	997	921	Do.
Clays and clay products (including all refractory brick):			
Crude (including refractory clay) do	553	835	Do.
Products:[6]			
Refractory (including nonclay brick) value, thousands	$15,183	$14,314	United States $8,951.
Nonrefractory do	$1,655	$1,656	Mainly to United States.
Diamond:			
Gem carats	26,810	38,333	United States 12,269; Belgium-Luxembourg 10,817.
Industrial (including dust) do	450,054	298,534	United States 245,636.
Fertilizer materials:			
Nitrogenous thousand tons	502	638	Mainly to United States.
Potassic do	7,242	8,278	United States 6,636.
Mixed do	532	539	United States 428.
Ammonia do	116	226	Mainly to United States.
Gypsum, crude do	3,692	4,187	Do.
Lime	235,779	309,354	Do.
Nepheline syenite	356,086	416,250	Do.
Pigments, mineral, including processed iron oxides	9,824	12,763	Do.
Precious and semiprecious stones, except diamond value, thousands	$2,382	$3,586	United States $1,095.
Salt and brine do	$5,111	$9,424	Mainly to United States.
Sand and gravel thousand tons	138	416	Do.
Sodium and potassium compounds: Sodium sulfate	178,109	146,396	Do.
Stone:			
Limestone, crude, crushed, and refuse thousand tons	1,218	1,420	Do.
Quartzite do	40	53	Do.
Rough building and crude stone, n.e.s do	303	631	Do.
Sulfur:			
Crude and refined do	3,284	4,101	United States 1,115.
Sulfuric acid, including oleum do	225	350	Mainly to United States.
Talc, steatite, soapstone, pyrophyllite	6,065	21,124	Italy 12,346; Canada 7,406.
Other, crude value, thousands	$44,913	$51,824	United States $14,034.

Table 3.—Canada: Exports and reexports of mineral commodities —Continued

(Metric tons unless otherwise specified)

Commodity	1975	1976	Principal destinations, 1976
MINERAL FUELS AND RELATED MATERIALS			
Coal, bituminous ---- thousand tons	11,695	12,977	Japan 11,685.
Coke from coal	99,998	204,242	United States 103,338.
Fuel briquets of coal and coke	2,220	1,734	Mainly to United States.
Gas, natural ---- million cubic feet	949,465	954,051	Do.
Peat	263,372	296,284	Do.
Petroleum:			
Crude ---- thousand 42-gallon barrels	262,455	182,682	Do.
Refinery products:			
Gasoline ---- do	4,876	2,763	United States 1,353.
Distillate fuel oil ---- do	6,597	1,772	United States 585.
Residual fuel oil ---- do	21,111	11,388	United States 9,871.
Lubricants ---- do	16	13	United States 6.
Other:			
Liquefied petroleum gas ---- do	36,919	17,565	Mainly to United States.
Asphalt ---- do	331	233	Do.
Petroleum coke and pitch coke ---- do	980	816	United States 644.
Total ---- do	70,830	34,550	
Mineral tar and other coal-, petroleum-, or gas-derived crude chemicals ---- do	284	314	United States 257.

ʳRevised. NA Not available.
[1]May include relatively minor quantities of certain shapes not normally included among semimanufactures.
[2]Partial figures, representing U.S. imports for consumption only.
[3]Includes some scrap.
[4]Largely, if not all, used in the production of heavy aggregate.
[5]Partial figures; exclude unreported quantities of scrap and sweepings valued in thousand U.S. dollars at $26,410 in 1975 and $19,587 in 1976.
[6]Partial figures; exclude unreported quantities of refractory products valued in thousand U.S. dollars at $2,709 in 1975 and $3,033 in 1976, and nonrefractory products valued in thousand U.S. dollars at $382 in 1975 and $305 in 1976.

Table 4.—Canada: Imports of mineral commodities

(Metric tons unless otherwise specified)

Commodity	1975	1976	Principal sources, 1976
METALS			
Aluminum:			
Bauxite ---- thousand tons	2,421	1,230	Guinea 523; Guyana 300.
Alumina ---- do	761	908	Australia 427; United States 294.
Metal including alloys:			
Scrap	7,011	8,936	United States 6,092.
Unwrought	ʳ18,302	22,545	United States 16,271.
Semimanufactures (including cable)	ʳ25,379	35,221	United States 31,795.
Antimony oxides	395	734	United Kingdom 614.
Chromium:			
Ore and concentrate, metal content	29,663	39,864	Philippines 21,641; United States 10,534.
Oxide and hydroxide	956	1,261	United States 1,106.
Copper:			
Ore and concentrate (including scrap), metal content	20,247	18,672	Mainly from United States.
Copper sulfate	807	1,406	Netherlands 967.
Metal:			
Unalloyed:			
Unwrought	10,908	9,122	United States 4,925; Chile 3,995.
Semimanufactures	5,435	10,067	United States 7,858.
Alloys, unwrought and semimanufactures (including cable)[1]	13,131	16,792	United States 10,915.
Iron and steel:			
Iron ore ---- thousand tons	ʳ5,340	3,329	United States 3,111.
Metal:			
Scrap ---- do	ʳ1,024	907	Mainly from United States.
Pig iron and related materials	11,941	16,705	United States 14,085.
Ferroalloys:			
Ferrochrome	41,109	21,923	Republic of South Africa 10,066; United States 6,863.
Ferromanganese (includes spiegeleisen)	35,701	25,054	Republic of South Africa 7,881; United States 6,064.
Silicomanganese	5,732	12,022	United States 4,950; Republic of South Africa 3,588.
Ferrosilicon	26,353	10,386	United States 7,992.
Ferrotungsten	45	77	Mainly from United Kingdom.
Ferrovanadium	100	105	All from United States.
Other	8,880	24,972	Dominican Republic 12,578; United States 3,226.

Metal: —Continued			
Steel, primary forms	106,572	22,348	United States 18,300.
Semimanufactures:			
Bars, rods, angles, shapes, sections:			
Wire rod	236,645	157,561	Republic of Korea 58,471; Czechoslovakia 37,029.
Other bars and rod	146,345	141,824	United States 79,557; Japan 43,435.
Angles, shapes, sections	190,655	231,098	United States 66,518; United Kingdom 42,363.
Universals, plates, sheets, strip	582,573	464,713	Japan 180,046; United States 165,781.
Rails and accessories	67,531	24,207	United States 21,952.
Wire	54,041	57,047	United Kingdom 19,043; United States 14,391.
Tubes, pipes, fittings	196,138	169,742	United States 86,430; Japan 53,941.
Castings and forgings, rough	108,826	123,392	United States 111,369.
Lead:			
Oxide	1,002	386	Mexico 166; United States 165.
Metal including alloys, unwrought and semimanufactures	2,434	3,278	United States 2,595.
Magnesium metal including alloys	8,386	1,812	United States 1,634.
Manganese:			
Ore and concentrate, metal content	69,773	118,972	Gabon 53,424; Brazil 33,054; Republic of South Africa 19,463.
Metal	5,390	6,553	Mainly from Republic of South Africa.
Mercury 76-pound flasks	2,133	1,817	Netherlands 618; United States 603.
Molybdenum: Molybdic oxide, gross weight	56	111	All from United States.
Nickel:			
Ore and concentrate (including scrap), metal content	17,894	24,566	Australia 10,362; United Kingdom 8,432; United States 5,449.
Metal including alloys:			
Unwrought	12,847	16,829	Mainly from Norway.
Semimanufactures	4,738	4,487	United States 3,398.
Platinum-group metals troy ounces	60,971	42,610	United States 28,717; Republic of South Africa 13,200.
Silver metal thousand troy ounces	13,506	1,901	United States 1,585.
Sodium metal	8,289	8,105	Mainly from United States.
Tin metal, unwrought and semimanufactures	4,680	4,429	United States 2,681; Australia 1,134.
Titanium:			
Dioxide, pure and extended	2,708	5,241	United States 3,743; United Kingdom 760.
Metal	405	439	Mainly from United States.
Tungsten ore and concentrate, metal content	1	--	
Zinc:			
Ore and concentrate (including scrap), metal content	756	3,449	United States 1,603; Peru 922.
Oxide and peroxide	1,479	1,808	United States 1,323; United Kingdom 291.
Metal:			
Blue powder	116	185	United States 161.
Unwrought	686	12,518	Netherlands 8,329; West Germany 2,031.
Semimanufactures	1,095	1,436	United States 1,229.
Zirconium metal alloys	222	181	Mainly from United States.
Other:			
Ores and concentrates (including scrap), gross weight	85,935	360,721	United States 189,444; Chile 55,356.
Oxides, hydroxides, peroxides of metals	1,479	1,808	United States 1,323; United Kingdom 290.
Base metals including alloys, all forms	1,625	2,418	United States 1,303; Norway 534.
Precious metals troy ounces	r467,189	252,847	United States 222,868.
NONMETALS			
Abrasives:			
Natural	16,094	8,131	Mainly from United States.
Grinding and polishing wheels and stones value, thousands	r$8,220	$9,021	United States $6,777.
Asbestos	5,166	6,002	Republic of South Africa 4,576.
Barite, crude	4,479	18,097	All from United States.
Cement	428,777	329,045	Mainly from United States.
Clays and clay products (including all refractory brick):			
Crude:			
Bentonite	242,183	274,094	All from United States.
Fire clay	43,320	33,340	Mainly from United States.
Fuller's earth	1,833	571	All from United States.
Kaolin (china clay)	148,378	176,750	United States 144,182; United Kingdom 32,568.
Other (including refractory clay)	143,156	152,998	United States 133,700.
Products:			
Refractory (including nonclay brick) value, thousands	r$62,302	$53,583	United States $46,334.
Nonrefractory do	r$24,853	$28,553	Italy $7,422; United States $6,447; West Germany $3,056.

Table 4.—Canada: Imports of mineral commodities —Continued

(Metric tons unless otherwise specified)

Commodity	1975	1976	Principal sources, 1976
NONMETALS —Continued			
Cryolite, crude	2,219	1,113	Denmark 1,057.
Diamond:			
Gem, not set or strung carats	157,978	199,538	Israel 60,810; Belgium-Luxembourg 52,621; Netherlands 25,199.
Industrial do	1,032,396	885,361	United States 509,039; Belgium-Luxembourg 161,028; Ireland 160,186.
Dust and powder do	489,830	620,926	Mainly from United States.
Diatomite	30,270	35,765	All from United States.
Fertilizer materials:			
Nitrogenous	88,383	152,752	United States 132,747.
Phosphatic:			
Phosphate rock	3,282,258	2,241,086	Mainly from United States.
Other	128,045	168,482	Do.
Potassic	44,458	45,134	All from United States.
Other, including mixed	96,983	104,730	Mainly from United States.
Fluorspar	157,222	137,310	Mexico 62,192; Spain 52,941; United States 11,009.
Gypsum	55,338	54,769	Mexico 47,788; United States 6,981.
Iodine	167	128	Japan 109; United States 19.
Lime	30,099	36,882	Mainly from United States.
Magnesite:			
Dolomite, calcined	2,239	3,062	All from United States.
Dead-burned or sintered	84,481	38,531	United States 35,760.
Other	3,081	4,096	Mainly from United States.
Mica, crude	5,111	4,696	Do.
Pigments, mineral, including processed iron oxides	5,548	5,706	West Germany 2,310; United States 2,223; United Kingdom 699.
Precious and semiprecious stones, except diamond value, thousands	r$8,733	$9,543	United States $2,798; Hong Kong $1,336.
Salt and brine	1,183,144	1,523,345	United States 1,160,692; Mexico 310,302.
Sodium carbonate (including sal soda)	141,175	189,186	Mainly from United States.
Sodium and potassium compounds, n.e.s.:			
Caustic soda	202,716	143,541	United States 114,200; West Germany 20,305.
Caustic potash and sodic and potassic peroxides	5,961	5,394	Mainly from United States.
Sodium sulfate (Glauber's salt)	22,638	29,265	United States 12,148; United Kingdom 7,754; Belgium-Luxembourg 7,690.
Stone, sand and gravel:			
Stone:			
Dimension:			
Crude and partly worked	53,380	44,494	United States 29,724.
Worked value, thousands	r$5,811	$5,849	United States $2,841; Italy $1,557; Portugal $1,074.
Limestone thousand tons	r3,618	3,873	All from United States.
Pumice and lava	28,563	10,356	Mainly from United States.
Quartz, silex and crystallized	1,550	863	Do.
Other, including crushed and broken	86,651	514,632	Do.
Sand and gravel:			
Silica sand thousand tons	r1,151	1,474	Do.
Other do	r2,105	2,303	Do.
Sulfur:			
Elemental	14,335	15,717	All from United States.
Sulfuric acid, including oleum	154,020	39,537	Switzerland 20,208; United States 19,323.
Talc, steatite, soapstone, pyrophyllite	30,428	46,397	Mainly from United States.

COMMODITY REVIEW

METALS

Exploration continued at a high level in all of the provinces and territories. The principal metals sought were copper, lead, zinc, gold, and silver. Continuing low prices, rising production costs, and weak domestic and foreign markets posed problems for producers of several of the metals.[e] Labor strikes at aluminum smelters in Quebec caused production losses in 1976, but operations returned to normal in 1977. The copper market remained poor; high inventories developed as a result of overproduction, and cutbacks were necessary, resulting in mine closures and deferred expansions. Higher prices for gold and a lower exchange rate to the U.S. dollar increased revenues from gold sales to U.S. markets and provided additional funds to gold-mining companies experiencing mining cost problems. Although iron ore mines operated at only 72% of capacity, some companies were developing new pellet and direct-reduction capacity. The performance of the major iron and steel companies exceeded GNP growth, although that of the smaller regional producers remained at low levels. New steelmaking capacity was under development at a number of operations. Lead mine output increased about 11% over that of 1976; revenues were higher, and stocks were drawn down. For nickel, the imbalance in world supply continued; the nickel price was soft and demand was low, leading to large inventories. Both Inco Ltd. and Falconbridge Nickel Mines Ltd. ordered plant shutdowns and nickel production cutbacks at Sudbury, Ontario. Several major zinc mines returned to normal production after labor problems in 1976. Zinc mine and refinery production was higher.

NONMETALS

Substantial capital expenditures for modernization were made at asbestos mines and mills to meet environmental standards. In the cement industry, shipments were slightly above those of 1976, and new capacity was under development. Demand for Canadian gypsum was strong, particularly in the United States. Relatively weak demand for other construction raw materials, including sand and gravel and clays, reflected the relatively poor year experienced by the construction industry. Deliveries of potash were up 30% over those of 1976. Potash Corp. of Saskatchewan, the Provincial Crown company, acquired additional potash mines and planned expansions. A new potash mine was planned in New Brunswick, following an agreement concluded between

Digitized by Google

the Provincial Government and Potash Co. of America. Canada continued as the world's largest exporter of sulfur; exports increased 20% over those of 1976.

MINERAL FUELS

Coal production exceeded that of 1976. Emphasis was on expansion of thermal coal mines to fuel the growing number of coal-fired powerplants. Slack coking coal production reflected weak world demand for steel, including that of Japan, which is Canada's principal export market for coking coal. Mine development projects providing for increased quantities of coking coal to Japan have been postponed.

Oil and gas exploration activity reached record highs. About 6.2 million meters were drilled in more than 6,000 wells, 80% of which were in natural gas exploration and development. This spurt in drilling activity was attributed to new provincial incentives. Discoveries, particularly of natural gas, were significant. Production of natural gas increased 2% over that of 1976, while output of crude oil decreased 1%. Exports of crude oil to the United States were reduced from 1976 rates, but natural gas sales to the United States were higher, owing to the provision of emergency supplies. Petroleum refinery capacity continued to grow, including completion of a major new refinery complex at Sarnia, Ontario.

Uranium exploration was widespread, covering all provinces and territories. According to the Department of Energy, Mines and Resources, 296 exploration project areas, many of which involved foreign participation, were recorded during the year. The most intensive activity was in northern Saskatchewan, where major new deposits were discovered or under development. The 1977 increase in production was attributed to expansion at existing mines and production startup at a new mine in northern Saskatchewan.

The Mineral Industry of Chile

By George J. Coakley[1]

Chile ranked as the world's second largest producer of copper, rhenium, and iodine, third in molybdenum, and was a major world producer of iron ore, natural nitrates, silver, and vanadium in 1977. The Chilean economy showed continued signs of improvement in 1977 as the gross domestic product in constant 1976 dollars increased nearly 9% to $9.4 billion. [2] Inflation declined to 63.5%. With exports of $2.2 billion, approximately 68% of which were mineral exports, Chile showed a balance of trade deficit of $69 million for the year. Continued low world copper prices and increased demand for imports contributed to this deficit.

Trends in production followed the 1976 pattern as copper, molybdenum, and silver reached record high output levels in 1977. Weak export demand kept iron ore production down, but improvement in domestic demand led to an increase in iron and steel output. Iodine production was up, but sodium and potassium nitrate production remained at depressed levels. Coal output held constant; petroleum and natural gas decreases were attributed to the depletion of current production sites.

Chile is placing major emphasis on the exploration and development of domestic coal, petroleum, and natural gas resources. The announcement of the first major offshore oil well, "Ostion," gave significant impetus to this effort.

Newly published reserve and resource data highlighted the magnitude of Chile's copper and molybdenum reserves, representing between 20% and 30% of known world reserves of each metal.

Government Policies and Programs.—In a major action to eliminate the bureaucratic delays in processing foreign investment applications, on March 18, the Government issued Decree Law 1748 modifying the previous legislation on foreign investment. According to the new law, there is no limit on profit and capital remittances, except that the capital must remain in the country for at least 3 years before it may be repatriated; exchange for profit and capital remittances will be available under the same conditions as apply to its purchase by local importers; there is no time limit on how long a foreign investment may remain in the country; foreign investors have the same rights and obligations as local investors, except that access to local credit facilities is limited; foreign-owned companies may opt to pay profits tax either at the normal rate for local companies, or at a rate of 49.5%, which is guaranteed fixed for 10 years from the contract date; the term, interest, commission, and other charges on foreign loans associated with foreign investments must be those authorized by the Central Bank; and existing foreign investment may become subject to the provisions of the new law by applying to the corresponding authority before March 18, 1978. The Foreign Investment Committee negotiates a separate contract with each foreign investor, stipulating the 3-year period within which the investment must be implemented. The only exception to this period is mining, where it is 8 to 12 years depending on whether exploration must first be undertaken by the investor. [3]

Decree Law 1759 published on April 30, 1977, modified the mining claim holding procedure under Chile's Mining Code. The new mining law raises the cost of holding mining claims to 52 pesos or about US$2.75 per hectare, an increase of over 1,600%. If fees are unpaid, the claim may be auctioned off after 1 year or forfeited outright after 2 years. If the claim holder is not working the claim, the fee is not recoverable. However, if the claim is being worked, the fee becomes tax-deductible. Furthermore, during the first 5 years that a claim is being developed, all startup costs, including claim

Digitized by Google

holding fees, are considered deductible from eventual profits. The new law is designed to expedite the development of the country's mineral resources and to serve as a further incentive to attract new foreign investment.[4]

Government efforts begun in 1974 to attract new foreign investment in the mineral industry of Chile bore their first major successes in 1977 as over seven foreign investment agreements were finalized, representing a potential capital inflow of over $2.4 billion.

In July a consortium of Falconbridge Nickel Mines Ltd., Superior Oil Co. of Houston, Canadian Superior Oil Ltd., and McIntyre Mines Ltd. signed a 30-year contract to undertake a $500 million development of the Quebrada Blanca copper deposit, located 75 miles north of Chuquicamata. The contract is contingent on the successful completion of a 4-year exploration and feasibility program costing up to $5 million. A 100,000—ton-per-year copper operation is envisaged. The consortium will hold a 51% share in the project, with the Government holding the remainder.

Noranda Mines Ltd. signed an agreement with the Government-owned Empresa Nacional de Minería (ENAMI) to explore, study, and, if attractive, develop the Andacollo porphyry copper deposit. Potential investment is estimated at about $450 million.

St. Joe Mining Corp. signed a $100 million agreement to examine and develop the El Indio gold, copper, and silver deposit near La Serena.

Foote Mineral Co. signed a contract agreement valued at $23 million to develop the lithium-bearing brines near Peña in the Atacama Desert. Metallgesellschaft AG has agreed to undertake the development of two lead-zinc projects near Asien each valued at around $35 million.

The Foreign Investment Committee also approved an agreement with Ataka Mitsubishi of Japan to undertake a $60 million feasibility and development project to exploit the Santa Clara iron ore deposit near Chañaral.

Late in December ENAMI sold 87% of its interest in Cia. Minera Disputada las Condes to Exxon Mineral International Inc. for an estimated $107 million. Exxon acquired Disputada's two operating mines and a smelter, but more importantly, Exxon indicated an intent to invest up to $1 billion to develop the Chilean company's large unexploited copper reserves.

PRODUCTION

Chilean copper and its major byproduct molybdenum and silver production exceeded 1976 record levels by 5% to 15% each. Smelter and refinery outputs of copper increased 4% and 7%, respectively. Iron ore production was held down in response to weak world markets and in an effort to reduce stockpiled ore levels. Iron and steel production increased to within 75% to 80% of capacity in response to increased domestic demand. Reversing previous trends, iodine production increased 16%. Continued problems in the nitrate industry were reflected in lower sodium nitrate and potassium nitrate output. Coal production remained constant as efforts continued to develop the known coal resources of the Magallanes area. Petroleum and natural gas production continued to decline; however, new offshore discoveries and the inferred potential of the offshore Straits of Magellan fields are expected to substantially boost production within the next 3 to 5 years.

[e]Estimated. [p]Preliminary. [r]Revised. NA Not available

[1]In addition to the commodities listed, lime and pyrites are produced but available information is inadequate to make reliable estimates of output levels.

[2]Data given are the nonduplicative copper content of ores, concentrates, precipitate, metal and other copper-bearing products measured at the least stage of processing reported in available sources.

[3]Figures presented are total blister and equivalent copper output including that blister subsequently refined in Chile and copper produced by electrowinning.

[4]Figures presented are total refined copper distributed into two classes according to method of refining.

[5]Excludes castings.

[6]Revised from "none."

[7]Includes natural sodium sulfate and anhydrous sodium sulfate, coproduct of the nitrate industry.

TRADE

Chile showed a negative trade balance for the first time in 4 years, with a 1977 deficit of $69 million. The deficit reflects an increased level of imports stimulated by two tariff cuts during the year, bringing tariffs down to a nearly uniform rate of 10%. This is part of the Government's policy to promote a free market system. Copper accounted for $1.14 billion or 43% of the $2.6 billion value of all exports. In the past, copper has provided from 75% to 80% of all export earnings. The reduction is attributed, in part, to continued low copper prices and also to Government efforts to encourage the expansion of nontraditional exports. Of the 1 million tons of copper exported in 1977, 18% went to Federal Republic of Germany 16% to Brazil, 14% to the United States, and 11% to Japan.

The other major mineral export earners in 1977 were, in million dollars, iron ore-$81, nitrates-$35.5, and molybdenum and other copper byproducts-$101.6. The $378 million value of petroleum imports represented 16% of all imported goods; coal and coke imports accounted for an additional $19.8 million. Crude petroleum imports totaling 27.6 million barrels were purchased from Iran (42%), Venezuela (31%), Ecuador (20%), Gabon (3%), and Iraq (3%).

COMMODITY REVIEW

METALS

Copper.—Continuing a policy of maximizing production levels, the Chilean copper industry in 1977 increased mine production 5% to a record high of 1,056,200 tons, smelter production 4% to 888,400 tons, and refinery output 7% to 676,000 tons. As shown in table 3, mine production was up at all mines except for a marginal drop at El Salvador and Disputada. Mining high-grade 2.34% copper ore during the year Codelco-Chile's Chuquicamata division accounted for 45% of all copper production. As the world's single largest copper mine, Chuquicamata mine production involved the removal of over 28.6 million tons of ore and 63 million tons of waste in 1977.

Corporación Nacional del Cobre de Chile (Codelco-Chile) reported that average production grades at Chuquicamata are expected to decline to 1.87% copper in the period 1978-82 and to 1.59% in the period 1983-86. During a comparable period, El Teniente is scheduled to maintain fairly constant ore grades, dropping only 3% from its 1977 level of 1.54%. El Salvador and Andina, however, will each decrease approximately 16% from the current head grades of 1.12% and 1.44%, respectively.

In anticipation of this trend in decreasing ore grades, Codelco-Chile is investing approximately $100 million per year to update and maintain its productive capacity and to increase the recovery of by products, particularly molybdenum. In 1977 at the Chuquicamata Division, Codelco upgraded mining equipment by adding the first of two new 28-cubic-yard electric shovels and twelve 170-ton off-highway haulage trucks. Addi-

tional projects to be completed between 1978 and 1981 included adding 80 new flotation cells to the scavenger cleaning circuit at the concentrator to increase capacity from 77,000 tons per day to 99,000 tons per day; converting eight sections of the tankhouse from electrowinning to electrolytic copper refining; and enlarging smelter casting capacity by adding a modified converter, two turboblowers, and an oxygen plant. The heat-recovery boilers are also being replaced.

At El Salvador, investments were directed toward equipment maintenance and replacement, improvement of the hydroelectric plant, and in increased mine area exploration. At Andina, work continued on the second stage of the molybdenite recovery plant and to expand copper mill capacity to 14,000 tons per day. Both projects are expected to be completed in 1978. Development of 4,800 meters of water control and diversion tunnels for the new Los Leones tailings dam at Andina continued as did design work to recover byproduct tourmaline from the mine in the future.

During 1977 the El Teniente Division completed work on the first stage of the 180 million-cubic-meter-capacity Colihues tailings dam and the addition of new pulp circuits and an automatic sampling and analyzing system in 23 circuits of the Colon concentrator. During 1977 100% of the basic engineering and 75% of the design engineering were completed on the Futura mine project at El Teniente. The existing

Digitized by Google

North and South mines are located in nearly exhausted softer secondary copper ore zones where conventional block caving mining methods are used. The Futura mine is an extension of the Teniente No. 4 level into the harder primary ore zone. A modified block caving operation and a 30,000-ton-per-day underground crusher will be installed to reduce the ore boulders to a minus 10-inch size treatable at the Colon concentrator. The project should be completed by late 1978.

Chile's competitive position and future strength in the world copper market lies in its tremendous copper resource base as shown in table 5. Measured and indicated reserves as shown represent about 20% of all known world copper reserves. Chile's efforts to develop its copper resources are highlighted under the discussion on foreign investment earlier in this chapter. In addition, active bidding is continuing for the rights to develop the El Abra and Los Pelambres deposits. A detailed description of the geology of the El Abra porphyry copper deposit was published during the year.[5]

Iron Ore.—Pressured by continued weak iron ore markets, a Government-owned but independently operated organization Compañia de Acero del Pacifico S.A. (CAP) cut back iron ore production for the second year in a row to allow for the further reduction of excess stocks. With a drop in demand, particularly for direct-shipping ore, CAP elected to close down the high-cost Incahuasi district, which includes the Desvio Norte and Cristales mines of the Sante Fe Division. Iron ore production decreases were experienced in all three divisions: El Algarrobo mines dropped 22% to 1,862,000 long tons, El Romeral mines down 19% to 3,287,000 long tons, and Santa Fe mines by 28% to 2,386,000 long tons. Drawing down stockpiles by 500,000 long tons, CAP marketed over 8 million long tons in 1977. Of this amount 92% was exported, representing a 16% drop in sales from those of 1976. CAP received an average price of $10.70 per long ton of iron ore for the year. New production of pellets is expected to increase the average price earned 2.5 times.

The $250 million Huasco Valley Project, which includes a beneficiation plant at El Algarrobo, a pellet plant at Huasco, and the Guacolda Port pellet storage and shiploading facilities, began operation in December 1977 with the official plant inauguration scheduled for March 15, 1978. A group of five Japanese steel mills led by Mitsubishi Corporation of Tokyo has contracted to purchase 33 million tons of Huasco pellets over the next 10 years.

A description of the geology of the El Romeral magnetite mine in relationship to a 30-kilometer-wide by 600-kilometer-long belt of magnetite and phosphatic apatite-magnetite iron ore deposits was also presented during the year.[6] On January 1, 1977, Chile withdrew its membership in the Association of Iron Ore Exporting Countries.

Iron and Steel.—Aided by a recovering domestic economy that absorbed 83% of all steel product shipments in 1977, CAP increased production to about 75% of capacity at the Huachipato steel complex. Pig iron production increased 7% to 432,000 tons, steel ingots 14% to 547,000 tons, and semifinished steel products 15% to 427,000 tons.

Annual sales revenues for CAP including iron ore, steel products, and byproducts increased by nearly 10% to $222 million. It was noted, however, that the average price received per ton of steel products was $385 for domestic market sales compared with only $251 for export sales. CAP suffered a net loss for the year as revenues were countered by the high-interest payments on the capital costs of the Huasco Valley and Huachipato modernization and expansion projects. In order to keep costs down, CAP has started a new policy of only producing on order. Because CAP operates independently, it must stand on its own financially. By the end of 1977, CAP had completely phased out its older Siemens-Martin electric furnaces and brought on-line two Linz-Donawitz converters with a combined capacity of 1 million tons. Second-stage milling capacity, however, is only 750,000 tons per year.

Molybdenum.—Chile maintained its position as the world's third largest molybdenum producer following the United States and Canada.

Production and shipments were up marginally for the year. Shipments from Codelco-Chile of molybdenum, ferromolybdenum, and molybdenum oxide amounted to 11,567 tons, with 29% of this amount consumed domestically. Approximately 64% of all molybdenite concentrates came from the Chuicamata mine as a byproduct of copper beneficiation. Chuquicamata is currently producing at a rate of 7,000 tons of molybdenum per year, and El Teniente at a rate of 2,500 tons per year. Newly published estimates of Chile's molybdenum reserves are

shown in table 5. Codelco-Chile is also planning on expanding molybdenite production at the El Salvador mine with a new $250,000 plant scheduled for opening in early 1979.

Precious Metals.—Byproduct copper production continued to be the principal sources of precious metals in Chile, accounting for 66% of all gold and 92% of all silver output in 1977. Silver production reached over 8 million ounces in 1977 but is expected to peak out in 1978 as Chilean copper production levels off and begins a decreasing trend for at least the next 5 years.

St. Joe Minerals Corp., as previously mentioned, signed an agreement to conduct further examination of the El Indio gold-copper-silver deposit. St. Joe would have an 80% interest in the project and is expected to announce development plans in mid-1978.

Uranium.—The Chilean Nuclear Energy Commission (CCEN) is currently considering proposals by Wyoming Minerals Co. to recover uranium from the copper tailings at Chuquicamata and by Union Oil Co. for exploration rights in the Aisen area of south-central Chile. Wyoming Minerals has a similar operation producing uranium from tailings at the Bingham copper mine of Kennecott Copper Corp. in Salt Lake City.

While there is no commercial production of uranium in Chile, CCEN is operating two experimental nuclear reactors, one at La Reina and one at Lo Aguirre.

NONMETALS

Iodine.—As one of the worlds three largest producers of iodine, the state-owned Sociedad Quimica y Minera de Chile (SOQUIMICH) reversed a trend in decreasing production as iodine output increased 16% to 1,652 tons in 1977.

Lithium.—Chile possesses approximately 1,270,000 tons of lithium, representing 64% of known world reserves. The lithium is found in the potassium-rich brines of the Salar de Atacama 280 miles from Antofagasta in northern Chile. The Foote Mineral Co. of the United States following 3 years of exploration and negotiation has reached an agreement with Corporacíon de Formento de La Produccion (CORFO) to study and possibly develop these deposits. The joint partnership will be called Sociedad Chilena de Litio (SCL). SCL has reached agreement with the Chilean Nuclear Energy Commission that the commission has the option to buy 10% of the lithium produced in any given year. All potassium chloride is the property of CORFO at exploration sites, but all magnesium, less 10% for CORFO, belongs to SCL.

Nitrates.—In 1976, SOQUIMICH experienced a slight drop in sodium nitrate production and a substantial decrease in enriched potassium nitrate production of over 33%. No new actions were taken during the year to improve the deteriorating condition of the nitrate industry in Chile.

MINERAL FUELS

Coal.—Production of bituminous coal by Empresa Nacional del Carbon S.A. (ENACAR), remained in the range of 1.2 million to 1.3 million tons for the year, with all coal consumed domestically. A December 1977 World Coal report states that the new thermoelectric plant at Quintero, Ventana II, will use 580,000 tons of coal per year. The plant, with a capacity of 210,000 kilowatts, is the largest in the country. With demand forecast to increase in the next decade, particularly with a Government policy of substituting coal for oil in industrial uses, work is continuing on feasibility studies to develop the estimated 4.7 billion tons of coal in the Riesco Island, Brunswick Peninsula, and the Natalles area of Magallanes.

Petroleum and Natural Gas.—Crude petroleum and natural gas production continued to drop in 1977 as the natural depletion of old wells continued. Empresa Na-

Digitized by Google

cional del Petróleo (ENAP), however, expects this trend to reverse itself by late 1978 as the newly discovered offshore Ostion well in the Straits of Magellan comes into production. When in full production, Ostion will help almost double national production to 16 million barrels per year. This will be a substantial boost to an economy that in 1977 depended on petroleum and its derivatives for 75% of its energy, but produced only 25% of its oil needs. (The figure approaches 30% to 35% if one includes liquid and natural gas.) Highlighting a report on petroleum development for the year, Chile Economic News noted that "reserves in the explored areas of Magallanes are estimated at 280 million barrels of oil and 5.5 trillion cubic feet of natural gas." Efforts are being made to interest foreign investors in exploration of zones where studies indicate good possibilities of petroleum deposits, to intensify exploration by ENAP in the Magellan Strait, and to develop projects for liquefaction and sale of gas from the Magallanes area.

A modification by Decree-Law 1089, which limits the role of the state may take in exploration and exploitation of oil deposits has opened new possibilities for investment by private companies and international concerns. A 35-year contract was signed in December 1977 with Atlantic Richfield Company and Amerada Hess Company for the exploration of a 500—kilometer stretch of Chile's Pacific continental shelf. The agreement calls for investments of from $240 million to $1.4 billion depending on the size of the deposits and stipulates that 60% of the profits will accrue to Chile and the remainder to the contractors.

In January 1978, ENAP will begin an operation known as the "Costa Afuera" offshore plan, drilling over 1,000 wells in the Magellan Strait. A 1969 study made in collaboration with the United Nations estimated the reserves in this area to be between 160 million and 190 million barrels of oil and between 2.6 and 3.5 billion cubic feet of natural gas. The program calls for two types of wells. Approximately 150 exploratory probes will help establish the limits of the deposits and indicate the best locations for fixed platforms such as those constructed in Loredo Bay, each providing the facilities for 9 or 10 drillings. The rest of the wells, about 800 of which are expected to be productive, are intended to extend and develop the oil beds. Oil from the Magellan Strait should begin flowing to refineries by September 1978, contributing a 25% increase to the national production at first and exceeding 40% within 5 years. The investment required is estimated at $273 million. Increased capacity for the present refineries has been planned to reach about 40 billion barrels by 1985. This project demands an investment of nearly $200 million.

Plans are also being made to tap the deposits of natural gas. Currently, the methane found in the Magellan Strait is not being put to commercial use, and only about 5% of the butane found in the oil wells is sold. Geographic conditions make construction of gaslines too costly. Construction of a liquefied natural gas plant and special transport vessels will require about $1 billion, but has been chosen as an alternative to make the export of gas in a liquid form possible.[7]

The Mineral Industry of the People's Republic of China

By K. P. Wang[1]

Whereas 1976 was a year of earthquakes, major political events, and industrial unrest, 1977 became the year of return to normalcy and record production levels for the People's Republic of China (China). Under Chairman Hua Kuo-Feng's pragmatic program for rapidly expanding industry along with agriculture, three or four thousand workers and managers had come from all parts of China to the famous Taching oilfield near Harbin in 1977 to learn the technology of this enterprise. An 8-year plan announced early in 1978 to end in 1985 calls for the development of 120 large-scale projects, including 10 iron and steel complexes, 9 nonferrous metal complexes, 8 coal combines, 10 oil and gas fields, 30 power stations, 6 new trunk railways, and 5 key harbors.[2] China was once more embarking upon rapid economic growth.

China's total gross national product (GNP) was over $320 billion in 1977, placing the country solidly within the first six countries of the world. China's GNP has been growing at an annual rate of up to 10% in recent years, although growth was much less in 1976. As an order of magnitude, minerals and metals together contributed more than 10% of the 1977 GNP.

A National Geological Conference was convened during July 1977, indicating the importance attached to this general subject for China's planners in their overall program of "four modernizations"—agriculture, industry, national defense, and science and technology. It was reported that the number of geologists exceeds 50,000 and drillers and prospecters total several hundred thousand.[3]

As of late 1977, China had completed a 1:1,000,000-scale geological map of China, a 1:2,000,000-scale geological map of Asia (published), many 1:200,000-scale and 1:50,000-scale regional geological maps within China, and a 1:4,000,000-scale tectonic map of China.[4] To support the "four modernizations" program, the Geological Survey or Geological Bureau plans to substantially ascertain China's mineral potential within 5 to 10 years, with particular emphasis on high-grade iron ore, water resources, fertilizer raw materials, coal in the south, and geothermal energy.

A leading member of the Chinese Geological Survey has stated that of more than 140 kinds of useful minerals known to the world, reserves of 132 of these occur in China in quantities large enough for exploration and use.[5] Also, China's reserves of 17 kinds of minerals are very large by world standards, including coal, oil, copper, tungsten, antimony, molybdenum, salt, magnesite, limestone, fluorspar, and phosphates. Many potential oil formations have been discovered around the country as a result of reconnaissance surveys over a million square kilometers of sedimentary basins. There has been success in finding coal in the south. China's "Mesabi-type" iron ranges in the north have been carefully mapped. Very large skarn-type copper deposits reportedly have been located. Work has been done on the relationship between tungsten mineralization and tectonics in Kiangsi Province. In the Hochih area of Kwangsi Province (known for tin in the past), three large and two medium-sized "colored metal" (generally means nonferrous) deposits reportedly have been discovered recently. An important selenium-bearing cupriferrous-pyrite deposit was found in Kwangtung Province; also, an extensive zeolite deposit in the Lishui district of Chekiang Province together with

Digitized by Google

many occurrences in nearby areas. A large "natural soda" deposit has been discovered in Tungpai Hsien of Nanyang district, Honan Province.

Another National Conference on Coal was convened in January 1978 to discuss work in the next decade and plans for further mechanization. China started to move toward developing or expanding specific coal mines for new markets, including promoting exports and buying foreign equipment and know-how to increase production. The Kailan (Kailuan) combine was brought back to the pre-earthquake output level of 70,000 metric tons per day (tpd) at yearend 1977, after most of its structures had been nearly flattened and all seven coal mines severely shaken and flooded 18 months ago. Shansi, the leading coal-producing Province, produced at a record pace of over 80 million tons per year (tpy). The 1977 output of two relatively new coal combines—Pingtingshan in Honan and Huaipei in Anhwei—was reported at about 11 million tpy each or roughly twice the production of a third fairly new combine, Feicheng in Shantung. Shensi Province completed the first phase of its largest "modern" coal mine called Fangshuping.

The Chinese petroleum industry was expanding in many directions, although nothing much had been said about the Takang field near the earthquake area. Finding more oil at greater depths and around the perimeters of existing fields of Taching and Shengli is most significant. The new Huapei or north China field had come into prominence, and samples of this and Shengli's oil were sent to Japan in anticipation of exports in the future. Oil and gas had been discovered in the central-southern part of east China, including the Sanshui (Samsui) basin of Kwangtung Province.

While concentrating on their own technical resources for exploration onshore, the Chinese were looking more into foreign equipment and know-how for offshore operations. Generally, they feel that over 40% of China's land area and half that much continental shelf area have potentially oil- and gas-bearing sedimentary rocks. Peking indicates that it had sailed research vessels to near Tiaoyutai and started exploration in the controversial South China Sea. As of yearend 1977, China was operating three foreign-built rigs, had a fourth on order, and finally purchased a fifth.[6] The program to build refineries, petrochemical facilities, pipelines, loading docks, and tankers was similarly moving ahead. Aside from Japan and other markets, China made an arrangement with France in January 1978 to ship half a million to a million tons of crude oil annually to France starting immediately.

Within the $2 billion deal (see below under Trade) to swap Chinese fuels for Japanese industrial plants and know-how, the role of steel stands out. The Chinese are clearly trying to produce more steel in the years ahead by new large plants, partly with the thought of cutting down on steel imports. To accommodate them and to gain a special position in the rapidly expanding China trade, the Japanese steel companies feel that helping to build producing facilities in China and provide transport and supporting services and know-how can earn them large dividends. Eventually slurrying Chinese coal and oil in Japanese pipe and then loading the slurry on to ships made by both parties is a good example of the future implications of this relationship.

Much basic construction on steel facilities has been done in China recently. The Wuhan steelworks was substantially completed, after several years of problems. The Anshan steelworks will be enlarged up to 12 million tpy steel capacity through rebuilding and modernization along the lines of the rejuvenated Yawata steelworks. Apparently, the Peking steelworks and possibly the Penchi steelworks will also be streamlined with Japanese help, on roughly half the scale of Anshan. A new 6-million-tpy steelworks is to be built in the Shangai area, with two blast furnaces of more than 4,000-cubic-meter capacity, three oxygen converters of 250 to 300 tons, continuous casting mills, and various rolling mills. Shansi may be another potential site.

China's 13 large foreign fertilizer plants were all scheduled to be in operation in a year or two. Simultaneously, many small and medium fertilizer facilities were also to be constructed. Reportedly, the Chinese have asked Kellogg to bid on additional coal-fired ammonia plants. Chemicals, petrochemicals, and industrial salts will be stressed. Production capacity of construction materials probably will be more than doubled in capacity in a decade, with equal stress on large and small cement works and additional emphasis on downstream products. Included in new nonmetallic facilities cited for good performance were the Shennan asbestos mine in Shensi, the Tangshan

Digitized by Google

kaolin plant in Hopeh, the No. 4 mica mine in Sinkiang, the Yaan mica processing plant in Szechuan, and the Changchow construction materials plant in Kiangsu.

China's biggest pyrite mine (open pit) being built in Yunfu, Kwangtung Province, was near completion. Kiangsi's new underground salt mine and works at Chingkangshan produces enough salt for the Province's 28 million people. The work on saline lakes and playas done by the Tsinghai Salt Lake Institute should be of importance to the chemical industry. Of aesthetic interest is a report[7] stating that 11 locations in Ninghsia Province have rich semiprecious stone resources, including agate, jasper, malachite, azurite, amethyst, and bronchantite that are important for carving, industrial, and jewelry use.

Two successful nuclear tests took place in 1977, China's 22d and 23d. The first was on September 17—a small (less than 20-kiloton) atmospheric blast. The second was on November 23, when an intermediate-range ballistic missile with nuclear warhead was launched in Kirin Province and guided to hit the Takla Makan Desert in Sinkiang.

The Chinese stated without details that their nuclear effort had become integrated, that they will redouble their efforts to attain world technical levels, and that very extensive resources of uranium had been ascertained.[8] One of the general areas mentioned for metalliferrous and uranium ore finds is the Yunnan-Kweichow Plateau. In earlier years, China's uranium came from places like Chuannan in Kwangsi and Weiyuan in Kwangtung.

The Chinese interest in nuclear energy appeared to be more intense than a few years ago. A news item states that the Chinese are prepared to talk to French nuclear power equipment representatives who are scheduled to accompany Premier Raymond Barre to Peking in early 1978.[9] Chinese nuclear power specialists visited Japan in 1972 and Canada in 1973. Very likely, the Chinese are thinking about large-scale nuclear power generation by the 1980's.

China's electric power industry, ranking about ninth in the world and having a capacity roughly one-tenth that of the United States, continued to expand.[10] Power output and installed capacity both rose by about 10% during 1977 (over that of 1976), the former being roughly 150 billion kilowatt-hours and the latter perhaps 43 million kilowatts. Whereas hydroplants possessed approximately one-third of China's electric power capacity, their contribution to electricity output was closer to one-fourth because of the intermittent nature of hydropower generation. Three-fourths of the thermal electric power was derived from coal and much of the rest from oil. All kinds of fossil fuels have been burnt directly, including low-rank coals, low-grade coals, crude oil, shale oil mixed with coal, and more recently "stone coal" (bone coal) presumably mixed with high-grade fossil fuels. Gas turbines are not yet important, although Szechuan Province is building many plants to use natural gas.

A major thrust was being made to build up the electric power industry—both large and small plants. The Chinese were thinking in terms of adding more than 50% capacity by 1980 and at least another 150% by 1983, compared with the capacity existing in 1977. They believe that China's hydropower resources total in excess of 500,000 megawatts—the largest in the world including 230,000 kilowatts in the Yangtze system and 100,000 kilowatts in the Yalu Tsangpu River of Tibet. China's coal resources are also very extensive by world standards, and its oil is potentially most important. Thus, there should not be any shortage of energy in China for decades to come, provided sound plans are implemented.

Over 40 large- and medium-sized hydroelectric and thermal generating units were put into operation in China during 1977.[11] More than a dozen such units were operating in faraway places like Sinkiang and Inner Mongolia. Thermal power stations were built near the pitheads of the Huainan and Huaipei coal combines for direct conversion to electricity. New power-generating units with combined capacity of 765 megawatts and about 500 kilometers of high-voltage transmission lines were built in 1977 as part of the effort to renovate the Peking-Tientsin-Tangshan power grid seriously damaged by the July 1976 earthquakes. When all four generating units are completed, the Touho thermal power station near Tangshan will be one of China's biggest. During the past decade, many small powerplants with combined generating capacity of 2.5 million kilowatts have been installed in Shantung Province.

PRODUCTION

China improved its position as one of the world's important mineral producers (see table 1). The country's position as a leading producer of bituminous coal, anthracite, tungsten, antimony, tin, manganese, mercury, bismuth, and salt had been known for some time. In recent years, China also achieved ranking among the first five in iron ore, steel, magnesite, cement, pyrite, phosphate rock, nitrogen fertilizers, asbestos, graphite, fluorspar, and high-grade talc. China has moved into the first 10 in the production of petroleum, natural gas, rare-earth elements, rare and high-purity metals, and barite for oil drilling. Generally, overall mineral and metal production increased significantly over that of 1976, as more idle capacity became utilized. China's mineral output and basic resource position have been described in a recent publication.[12]

Even though Kailan was producing at about half of its historic peak annual rate because of the rehabilitation work following the earthquakes, China's coal output apparently registered up to a 10% gain over that of 1976. The oil industry attained the yearly capacity of 100 million tons, with Taching adopting more efficient recovery methods and Takang still trying to fully overcome the dislocations resulting from the earthquakes. Natural gas production reportedly gained more than a fifth over that of 1976 and was approaching the 100-billion-cubic-meter annual level. An increasing share of the gas was being utilized with the completion of more local and faraway pipelines.

The steel industry was clearly getting out of its doldrums, with production in the second half of 1977 at close to plant capacities. Basic construction at various steel plants was also being completed so that the 30-million-tpy output level became clearly in reach. Steel projects implemented would add 10 to 15 million tons of annual capacity to China's total within 5 years. The cement industry continued to move ahead in 1977, with China replacing the Federal Republic of Germany as the world's fourth largest cement producer.

The famous export metals like tungsten, antimony, and tin appeared in lesser quantities in world markets than in 1976, but this did not mean that production had decreased. Larger quantities and greater varieties of "rare metals" were produced. China further improved its position in both nitrogenous and phosphatic fertilizers, spurred in part by the overall growth in the use of fuels and despite the fact that half the large new chemical fertilizer plants had not yet really come in to play. The Chinese salt industry, which mainly utilized seawater, approached the output of the United States—the only larger salt producer than China. China remained prominent in nonmetallics like pyrite, magnesite, asbestos, barite, fluorspar, and talc.

Table 1.—People's Republic of China: Estimated production of mineral commodities

(Metric tons unless otherwise specified)

Commodity[1]	1975	1976	1977[p]
METALS			
Aluminum:			
Bauxite, gross weight[2]	990,000	990,000	1,200,000
Alumina, gross weight	520,000	520,000	650,000
Metal, primary, refined	200,000	200,000	250,000
Antimony, mine output, metal content	12,000	12,000	12,000
Bismuth, mine output, metal content	250	250	250
Cadmium, smelter production	110	110	110
Copper:			
Mine output, metal content	100,000	100,000	100,000
Metal, smelter	100,000	100,000	100,000
Metal, refined	150,000	150,000	150,000
Gold, mine output, metal content troy ounces	50,000	60,000	60,000
Iron and steel:			
Iron ore, gross weight[3] thousand tons	65,000	65,000	65,000
Pig iron and ferroalloys do.	32,000	30,000	30,000
Crude steel do.	29,000	27,000	30,000
Rolled steel do.	22,000	20,000	23,000
Lead:			
Mine output, metal content	100,000	100,000	100,000
Metal, refined	100,000	100,000	100,000

Pyrite, gross weight[6] do	2,000	2,000	2,000
Salt do	30,000	30,000	35,000
Sulfur:			
Native	130,000	150,000	170,000
Content of pyrite	900,000	900,000	950,000
Byproduct, all sources	120,000	320,000	330,000
Total	1,150,000	1,370,000	1,450,000
MINERAL FUELS AND RELATED MATERIALS			
Coal:			
Anthracite thousand tons	20,000	20,000	30,000
Bituminous and lignite do	450,000	460,000	470,000
Total do	470,000	480,000	500,000
Coke, all types do	28,000	28,000	28,000
Gas, natural:			
Gross production billion cubic feet	[r]2,300	[r]2,900	3,400
Marketed production do	[r]2,000	[r]2,600	3,100
Petroleum:			
Crude (including crude from oil shale) thousand 42-gallon barrels	584,000	657,000	730,000
Refinery products do	475,000	548,000	650,000

[p]Preliminary. [r]Revised.

[1]In addition to the commodities listed for which quantitative estimates of output have been made. The People's Republic of China is known or is believed to have produced the following commodities for which no estimates, even of order of magnitude, have been prepared, owing to a paucity of general information upon which to base an estimate: Arsenic, chromite, nickel, titanium minerals, uranium, boron minerals, various clays (including kaolin), feldspar, lime, mica, various industrial and dimension stone, sand, and carbon black. Other unlisted commodities also may be produced.

[2]Diasporic bauxite; includes estimated 163,000 metric tons annually of production for refractory applications.

[3]In terms of 50% Fe ore.

[4]Data are for years ending June 30 of that stated.

[5]Source: British Sulfur Corp. Ltd. Statistical Supplement No. 18, November-December 1978.

[6]Sulfur content of pyrite has been listed under "Sulfur."

TRADE

China's overall foreign trade has not shown much change in the last few years. A significant part of imports in 1973-74 was for industrial equipment and plants; however, subsequent imports were weighed much more heavily in metals, fertilizer, and nonmineral materials. The Chinese have tried hard to export more oil and other products so as to have foreign exchange to buy equipment and plants for industrialization. There was a trade deficit of about $1.5 billion in 1974; however, a somewhat balanced situation existed in 1976. Trade in 1977 at possibly $14.5 billion was up slightly

Digitized by Google

from that of 1976, and there was a surplus of up to $2 billion in the latter year.

The trade outlook at yearend showed that some major changes were in the offing, with projected increases in overall volume and larger sales of fuels along with purchases of "tools" of industrialization. Initially, more emphasis on trade with Japan and Western Europe rather than the United States was expected because of Sino-American normalization problems. The European Economic Community or the Common Market was about to make a 5-year agreement with China to expand trade both ways and with "favorable treatment." Sino-West European trade totaled about $2.5 billion in 1976 and possibly $2 billion in 1977, with the foreign exchange balance shifting from $390 million in favor of the Community in 1976 to perhaps $100 million in favor of China in 1977. According to an unconfirmed report at the turn of the year, China apparently ordered about $300 million of mining equipment from Britain for extracting coal and other minerals and a second similar order may follow. The equipment would be used to develop Chinese coal mines to supply an electric powerplant to be built in Hong Kong with up to 3.5 million tpy of coal starting in the early 1980's. Total U.S.-China trade has dwindled to about a third of a billion dollars in 1976 and only $375 million in 1977, and minerals were not important.

Total trade with Japan was about $3.8 billion ($2.3 billion exports by Japan) in 1975, $3.0 billion ($1.7 billion exports by Japan) in 1976, and reportedly $3.5 billion in 1977. The major trading deal signed with Japan in early 1978 involving $20 billion total both ways during an 8-year period, would be in addition to normal trade.[13] This move indicates a pragmatic approach by Chinese leadership to build up a modern industrial base, and Japanese interest in gaining a foothold on China's expanding market. Japan will sell $7 to $8 billion in plants and technology and $2 to $3 billion in construction materials during the first 5 years. There could be a dozen large industrial plants covering steel, copper, fertilizers, natural gas, petrochemicals, building materials manufacture, leader, television, plastics, conveyors, etc. The Chinese will ship about 47.1 million tons of crude oil and 8.4 to 9.2 million tons of coal (including 5.1 to 5.3 million tons of coking coal and 3.3 to 3.9 million tons of steam coal) during 1978-82 plus additional tonnages of these fuels in 1983-85. China initially asked for the most favorable possible terms of payment for Japanese products but finally agreed to the principle of deferred payments whereby Japan would loan China some of the money with interest no lower than 7.5%.

Table 2.—People's Republic of China: Apparent exports of selected mineral commodities[1]

COMMODITY REVIEW

METALS

Aluminum.—Because of the rapid build-up planned for the Chinese electrical industry and the anticipated expansion of the oil, gas, coal, and steel industries as well, demand for aluminum and copper should also increase sharply. Chinese aluminum output rose to at least 250,000 tons estimated for 1977. Recent additions to the aluminum capacity had been in the form of small plants of 20,000 to 30,000 tpy although China needs to construct a few large new plants. The only sizable aluminum plant that the country has was still the relatively old 100,000-tpy Fushun reduction plant in northeast China. Since aluminum reduction requires considerable electrical power in the process, the two industries must be built up at the same time.

More than a dozen locations have been mentioned as sites where small aluminum plants have been built, and it may be prudent to guess that only two-thirds of these have operating reduction facilities. The Sanmen Gorge plant in Honan-Shansi border and the Yiliang plant 80 kilometers southeast of Kunming have been described as having two lines of potlines each. Other unconfirmed plant locations are Lanchow in Kansu, Taiyuan in Shansi, Wuhan in Hupeh, Changling in Kirin, Tsingtao in Shantung, Chengtu in Szechuan, Hofei in Anhwei, and very recently Paotou in Inner Mongolia.

London's World Metal Statistics estimates that "western countries" exported 330,800 tons of aluminum to China in 1975, 133,700 tons in 1976, and only perhaps 25,000 tons (incomplete) during the first half of 1977. During 1976, the United States exported 37,350 metric tons of aluminum to China, and Japan exported 10,000 tons. In the first 10 months of 1977, U.S. aluminum exports to China were down to about 5,000 tons and Japanese exports rose to 29,000 tons. In September, Tokyo sources estimated that combined aluminum sales from five Japanese companies could total 100,000 tons for 1977, although international trade sources say that actual sales may have been only about 45,000 tons. It is clear, however, that the Japanese with large inventories were anxious to sell. Mitsubishi Light Metal was thinking about a 3- to 5-year contract for delivering 15,000 to 20,000 tons annually to China. For the world as a whole, known sales of aluminum to China may have been 150,000 to 160,000 tons during 1977, over 100,000 tons from the western countries excluding Japan. Some of the traditional suppliers were Alusuisse of Switzerland, Pechiney of France, and Alcan of Canada. According to trade sources again, China obtained relatively steady supplies of foreign aluminum throughout 1977. Also, it may be that the overall level approximates what China might need to import annually until its industrialization program accelerates.

Antimony.—China's output of antimony had been in excess of 10,000 tons per year (tpy) for many years and was perhaps 12,000 tons in 1977. Some feel the Chinese output of antimony had occasionally reached 15,000 tpy in recent years. About half of the Chinese antimony had been generally exported in recent years. However, international prices dropped to just over $1 per

Digitized by Google

pound in early 1978 (recovered to $1.30 in April) and world demand was sluggish because of economic difficulties in many countries. Historically, China was by far the world's largest producer. The market for antimony for use in small arms and shrapnel shells had vanished many decades ago, but demand for use of batteries, bearings, type metal, solder, and standard munitions held firm and consumption in flame proofing, pigments, and ceramics became stronger. Bolivia with its complex metal ores, South Africa with its gold-antimony ores, and China were again the world's three leading antimony producers in 1977. Bolivia was trying to get the three together to talk about antimony and had itself recently sent several groups to China to discuss cooperation and exchange of information on antimony. At yearend 1977, Bolivia proposed a meeting of the three countries in La Paz during March 1978. Hitherto, South Africa has had technical problems (such as high arsenic) to resolve and it has not been particularly enthusiastic about conferring with the Chinese.

China's technical and commercial knowledge of this metal is excellent. The bulk of the Chinese antimony traditionally had come from the southwestern part of Hunan Province, headed by the Hsikwangshan mine, which may have had more than a million tons of mine antimony reserves by itself. Kwangtung Province ranked a distant second in potential and output. Under present low-price conditions coupled with the low demand, the antimony business is hardly attractive. However, overall resources are large enough to support any reasonable output level necessary to satisfy world and Chinese market requirements.

As usual, the Chinese tried to derive maximum benefit from antimony exports in 1977, selling more in periods of good prices and holding back when demand was low. There being no special production problem for Chinese antimony, surpluses were simply added to the stockpiles and shortages were made up from the stockpiles. Judging from recipient countries, Chinese exports of antimony were just over 5,000 metric tons in 1975, just under 5,500 tons in 1976, and very likely 5,000 to 6,000 tons again in 1977. The United States imported 191 metric tons of metal and 1,169 tons of oxide in 1976 and 438 tons of metal and 355 tons of oxide in 1977. The Japanese imported 819 metric tons of concentrates (analyzing 50% to 60% antimony) and 811 tons of metal in 1976 and 1,248 tons of concentrates and 1,133 tons of metal in 1977.

Copper.—Despite obvious mounting needs, the copper picture has not been clarified to any degree, partly because nonferrous metals are seldom reported. China probably still has copper stocks from previous imports, and the lull in basic construction and metal consumption, on account of recent difficulties politically and otherwise, has temporarily cut down on demand. There is no question, however, that the country can consume in excess of 300,000 tons of copper annually, of which not much more than half can be supplied domestically at the present time. Although little developed, the Chinese have recently claimed that their copper resources are substantial. Earlier reports noted that porphyry copper occurs in the Chilien Mountains of Kansu Province, the Chungtiao Mountains of Shansi Province, and in Chekiang Province. Current reports state that extensive high-grade skarn copper deposits have been found in the middle-lower reaches of the Yangtze River and "many other areas" as well.[14]

Photos of the modernized Tungchuan underground copper mine in Yunnan and the Tungling copper mine in Anhwei have been published in recent issues of the China Pictorial. A little earlier in the year, a large complex-metal copper deposit reportedly was discovered in the Tahungshan area of Yunnan Province.[15] An open pit copper mine near Tayeh, Hupeh Province, was said to be of both archeological and commercial interest. China apparently does not have a single big copper facility, and the largest mine is less than 20,000 tpy of mine copper in capacity. There is no news about the Shenyang and Shanghai smelters, which are old and only medium-sized at best. Small copper smelters and refineries have been mentioned for Lanchow in Kansu, Urumchi in Sinkiang, Taiyuan, Wuhan, Kunming, and in Anhwei Province and Hainan Island. Of great potential importance is a Chinese statement that a large copper refining facility would be bought from Japan in the near future, and the conjecture is that the Mitsubishi Metal Corp. will furnish this plant.

Chinese copper imports averaged about 100,000 metric tons annually during 1973-74. In 1975-77, yearly imports were closer to 30,000 to 40,000 tons, not counting what might have been bartered. Despite very low prices, China had not resumed large-scale

Digitized by Google

copper purchases as of late 1977. The Chinese had made a bold bid to consolidate and expand copper supplies from Africa by handing over the 1,100-mile Tanzam Railway they built, in the presence of the Presidents of Tanzania, Zambia, Zaire, and Botswana in July 1976. They have a long-term contract to obtain 50,000 tons of mine copper per year from Zambia, but open market statistics have not confirmed such a high level. The Chileans exported an average of more than 45,000 metric tons of copper to China yearly during 1972-74, but tonnages became uncertain for subsequent years because of Chile's political changes. However, to repay a Chinese loan, the bartered tonnage by Chile would still be at least 25,000 tons yearly. In helping to develop the Tintaya mine in Peru, the Chinese were scheduled to be repaid by about 40,000 tons of copper annually plus 10,000 tons each of lead and zinc; these tonnages are a little higher than that actually transpired. Papua's Bougainville mine supplied China with a 10,000-ton shipment of copper concentrates in early 1976, and negotiations were underway to obtain additional tonnages. However, Chinese copper imports from the Philippines might well expand, in view of Chinese interest in selling crude oil. With the November 1977 contract by Atlas Consolidated to supply China with 40,000 tons of copper concentrates valued at $12 million, total such exports by the Philippines from their start in 1975 had reached $36 million.

Iron and Steel.—After suffering a severe setback during 1975-76, the Chinese steel industry staged a strong comeback in 1977. Much was said about the improved performance of the steel industry during the latter year; beginning in the spring of 1977, production showed great increase and, in many cases, established records. The turnaround forshadowed a successful year in 1978 when production could conceivably exceed 30 million tons per year for the first time in China's history.

Recognizing that steel output must be pushed up sharply to meet industrial needs in the years ahead, the Chinese have set the long-range target of surpassing U.S. levels by the end of the century. Even by the early 1980's, plans underway indicate that China's steel production can reach the 40-million-ton annual level, and by 1985 the hope is to produce 60 million tons. Various developments point to these probabilities. A hematite iron ore beneficiation mission visiting the United States in mid-1977 indicated that Chinese planners intend to start large-scale development of the extensive low-grade iron deposits in the north. Chinese technical steel missions were sent to Japan and Western Europe late in the year. Japanese steel trade missions have visited China on many occasions. In 1977, inquiries were made of the presidents of Nippon Steel and Sumitomo Metal Industries to build 6-million-tpy steel facilities. Interest is growing in constructing large blast furnaces and basic oxygen converters. China already buys high-grade iron ore from Australia and has recently been negotiating with the Brazilians for supplies. In January 1978, Tokyo reported that the Japanese had been asked to help construct 20 large integrated steelworks in China to help meet end-of-the-century long-range targets.[16]

Japan has been China's leading steel supplier by far, sending about 2.9 million tons of products to China in 1974; 2.8 million tons in 1975; and 3.5 million tons in 1976. China purchased approximately 4.8 million tons of steel from Japan for shipment during April 1977 to March 1978. West Germany probably ranks a distant second to Japan in supplying finished steel to China in recent years, and there are 10 other countries that furnish 20,000 to 70,000 tons annually. China has imported 300,000 to 700,000 tons of scrap annually in the 1970's (mainly from the United States), and 300,000 to 500,000 tons of pig iron annually in recent years (mainly from Australia). During 1974-76, China's imports of iron ore have averaged nearly 3 million tons per year, roughly half each from Australia and North Korea.

Although large steelworks provide the bulk of China's production, the role of medium and small plants has been much more significant than in other major countries in the world. Medium and small steelworks have together provided one-fourth to one-third of China's total steel output in recent years. A current article gives some insights.[17] A rapid growth of this sector was claimed for 1958-60, followed by a very severe cutback the next 5 years. A new buildup took place during 1966-72, and output in 1973 reached high levels. However, production in the 3 years 1974-76 added together was said to be not as much as the quantity produced in 1973. There was a turnaround in 1977. Each of 10-odd Provinces and Special Districts (including Kiangsu, Shantung, Honan, Hopeh,

Digitized by Google

Kwangtung, Liaoning, and Anhwei) reportedly produced more steel than the national total before Liberation. In 1977, there were a total of more than 50 steelworks of 50,000-tpy capacity in existence or being constructed and over 500 smaller steel plants spread out in the country. Actually, a number of the medium-sized plants have annual capacities of hundreds of thousand tons.

The future of Anshan, China's leading steelworks by far, looked bright once more at yearend 1977, especially when compared with the miserable performance in 1976 when output was much below the 6- to 7-million-tpy steel ingot capacity. Production reportedly increased from month to month beginning in the spring of 1977 until records were claimed in the winter months. The most interesting news concerning Anshan was reports by officials of Nippon Steel regarding their talks with the Chinese about doubling Anshan's capacity in 3 years, to roughly 12 million metric tons of steel products annually.[18] Chinese intentions seem serious, although time schedules discussed may not be quite realistic. In pig iron, the plan would be to import 13 or 14 large blast furnaces to replace the smaller ones now in use and rebuild some existing bigger blast furnaces. In steelmaking, the plan would be to replace old open-hearth furnaces with large size, top blown oxygen converters.

The overall program to rebuild Anshan would be patterned after the reconstruction program of Japan's Yawata Steelworks. New equipment for pretreatment of raw materials would also be installed, no doubt along with fabrication facilities. Anshan's last or 12th blast furnace—2,580 cubic meters and capable of producing 1.5 million tons of pig iron annually—was blown in on December 29, 1977. Reportedly, China was combining two blast furnaces into one at Anshan so as to make the new furnace "the country's largest";[19] this may be the furnace mentioned above. Anshan's No. 11 of 1,000 cubic meters started operations in 1972; its only other sizable blast furnace is rated at 1,513 cubic meters, and the smallest one seems to be 585 cubic meters in size. The world's and Japan's largest blast furnace is about 5,000 cubic meters, but what was discussed with the Chinese was probably smaller. Anshan had about 25 open-hearth furnaces and two 120-ton basic oxygen furnaces (BOF); it is quite likely that the Chinese are thinking about installing the necessary number of 100- to 150-ton BOF's within the next 5 years, so as to produce 12 million tons of steel products. Anshan has mostly 4-cubic-meter electric shovels and 20-ton trucks at the open pit mines now, and it will need larger size equipment for expanded output.

The Peking, "Capital," or Shihchingshan steelworks apparently has done reasonably well in recent years.[20] With two blast furnaces of 1,000 to 1,200 cubic meters and two smaller ones, the Peking steelworks has had the capacity to produce about 2 million tons of pig iron yearly for some time. However, its No. 2 sintering plant and its No. 4 coke plant apparently had not been completed until late in 1977. Since steel output reportedly has been raised fivefold in the last decade, Peking's current yearly steel capacity may be close to pig iron capacity. Thus, Peking has become an important integrated steelworks, with ferroalloys, refractories, cast iron, and nonferrous facilities as well. Details on steel making and rolling facilities are not known, although this complex certainly has open-hearth furnaces, oxygen converters, and a blooming mill. Currently, iron ore comes from the Lungyen and Chienan mines which are located within an iron range with extensive low-grade ores. The Peking steelworks of the future could be streamlined with new equipment and considerably expanded in the process. The Japanese steel firm Nippon Kokan apparently has been asked to help renovate and expand this steel center to as much as 6 million tpy.

The integrated Wuhan steelworks is capable of producing more than 2.5 million tons of steel ingot per year. However, during all of 1976 and possibly half of 1977, this plant has had serious political difficulties which had the net effect of greatly slowing down production. It was not until early October 1977 when daily steel and pig iron production were restored to 6,000 metric tons and 7,300 metric tons, respectively. Wuhan has four 1,400- to 2,000-cubic-meter blast furnaces, four byproduct coke plants (the last one completed around May 1977), eight mostly 500-ton open-hearth furnaces, a hot rolling mill, a plate mill, and a rail mill. Very possibly, Wuhan will soon be building large BOF's to complement or replace the open hearths. West German and Japanese fabrication equipment worth $550 million, including a 3-million-ton hot strip mill, a 70,000-ton silicon Sendzimer steel mill, a million-ton cold strip mill, and a continuous casting mill, were in the process of being

Digitized by Google

installed, although startup may be delayed until 1979. Wuhan has at least four iron mines, including the Tayeh open pit and the Chengchai and Tahungshan underground mines.

Shanghai with possibly eight small steelworks and an aggregate annual ingot capacity of considerably more than 3 million tons also has had operational difficulties in recent years, although not as severe as Wuhan and Taiyuan. However, the situation in Shanghai had returned to normal by the second half of 1977. During the first 10 days of January 1978, Shanghai's daily steel output reportedly averaged 13,700 metric tons. In early 1978, several Japanese newspapers reported that Nippon Steel, aided by other Japanese steel producers, will help build a 6-million-tpy steelworks in the Shanghai area for completion in the mid-1980's at a cost variously estimated at $1 to $2 billion in terms of foreign exchange. It is highly probable that much of the basic raw materials needed will be imported.

The Taiyuan steelworks, rated at just over a million tons of annual steel capacity and possessing China's only foreign-built BOF (Austrian, 55 tonners), had been worked haphazardly until late 1977. The largest of Taiyuan's four blast furnaces is rated at 1,200 cubic meters with another one close to 1,000 cubic meters in size; these furnaces together seem to be capable of producing over 2 million tons of pig iron yearly. A new large open pit iron mine called Okou altogher with a beneficiation plant were brought into production in early 1977 to supply Taiyuan. The Paotou steelworks in Inner Mongolia has added a third large blast furnace; the first one built was 1,513 cubic meters in capacity. The Penhsi (Penchi) steelworks in southern Liaoning Province, originally rated at about 1.5 million tpy of pig iron capacity, has been built up into an integrated steelworks. The last coke oven plant (65 slots) was completed by mid-1976. Penhsi's No. 2 steel plant, whose construction began in 1972, started operations on August 6, 1977; among its facilities are "large" oxygen top blown converters built by Chinese engineers. Substantial espansion of Penhsi with the help of the Japanese may also be in the works.

Tin.—Very little new information came out of China on tin. However, exports were clearly down, judging from reported imports by consuming countries. A reasonable guess is that total Chinese tin exports dropped from nearly 15,000 tons in 1975 (highest tonnage for more than a decade) to 7,000 tons in 1976 and only 3,000 tons in 1977. Correspondingly, U.S. imports of tin from China declined from nearly 6,400 tons in 1975 to just over 1,700 tons in 1976, and probably less than 400 tons in 1977. During the last 5 years, the Billiton subsidiary of Dutch Shell handled a large part of Chinese tin exports worldwide. Some of the 1974-75 period Chinese tin reaching international markets was old tin, whereas more recent exports were mostly high-grade new tin. The Soviet Union no longer obtains much tin from China, but Finland became a purchaser of possibly 400 tons in 1977. For whatever reasons, the Chinese have not been selling much tin.

Some people feel that production is down from the generally estimated 20,000-tpy annual level. It is clear that consumption has been increasing steadily during the seventies, except for 1976. This trend should continue, and in fact, probably will rise to a higher plateau by the early 1980's. Even now, consumption of tin in China may be pushing 10,000 tpy. The 120,000-tpy ETL tinning plant at Wuhan, which would consume about 600 tpy of tin, will soon be in operation; China probably had been saving some tin for this plant rather than exporting it. Unconfirmed reports say that Mitsui people are helping the Chinese to build tinning facilities in north China that may need thousands of tons of tin per year. More important is that China is planning to build various large steelworks within 5 years, and no doubt these will have tinning lines. Thus, unless China finds and produces more tin in the future, there could well be a shortage.

Chinese tin reserves are undoubtedly large by world standards, and generally credited at 1 to 2 million tons of tin content. The most important tin center is still Kuchiu in Yunnan, which had been renovated in the late 1950's and modernized in the early 1970's. The lode tin ore is high grade but contains impurities; product quality has been recently improved which implies addition of better refining facilities. It is not known whether the earthquake in Yunnan during 1976 affected Kuchou's operations. China's No. 2 tin center is the general district of Fuhochung in Kwangsi Province, which is placer and has clean tin. The placers are 1 to 5 meters thick and probably occur in narrow river plains. A new placer district in Kwangsi is Chiumou. The relatively new districts of Haifeng and

Digitized by Google

Chaoan in Kwangtung Province are said to have reserves of over 200,000 tons of tin each. A tin mine called Pantan was reported for Kwangtun, producing about 10 kinds of "rare" metals as byproducts.

Tungsten.—China's tungsten resources are probably the largest in the world, and overall reserves may be about 100 million tons of 1.0% to 2.5% WO_3 ore, as an order of magnitude. Consumption has steadily grown to the present level of 5,000 to 6,000 tons of concentrates and exports have ranged from about 25,000 tpy of concentrates in the early 1960's to 12,000 tons in 1973 and perhaps 6,000 tons in 1977. However, output does not vary according to domestic consumption and exports, since management of production and sales are under separate groups. For a country very much aware of national security matters, China could easily have 50,000 tons of stocks. If China builds up its steel industry as announced and does not find new large resources, then exports might well decline further. World prices were good ($130 per short ton unit or 10 pounds of WO_3) in late February 1978, but exports remained low. China participates in United Nations Conference on Trade and Development and Primary Tungsten Producers Association meetings in Geneva but have thus far said very little about its tungsten industry.

Most Chinese ore is high-grade wolframite from Kiangsi Province, but scheelite from Hunan Province has become important, and significant deposits have also been found elsewhere in southeast China, particularly in Kwangtung Province. There are probably a dozen mines capable of producing 500 to 2,000 tons of concentrates annually as well as many other smaller mines in the "tungsten belt" along the Nan Ling Range. The best known mines in Kiangsi are Hsihuashan, Tachisan, Kweimeishan, and Pankushan. Considerable exploration has been done in recent years on the known deposits of Kiangsi, including use of modern geophysical methods and study of the correlation of tungsten mineralization with tectonic systems; apparently, many hidden ore bodies have been discovered which helped to rejuvenate the tungsten mines in this Province.

A typical large Kiangsi mine in the Tayu district has hundreds of steep veinlets in a mineralized zone of several square kilometers, with reserves of possibly 100,000 tons of WO_3 contained in ores analyzing 1.2% WO_3 and 0.5% tin, and it generally produces 100 to 1,000 tpy of finished tungsten concentrates. Mining at 100- to 250-meter depths is well engineered and at least semimechanized, with daily ore production in the 2,000-ton range. Hunan mines are best known for scheelite and one of these may be Yangchiatan. However, small wolfram mines located in Tucheng County of this Province apparently were doing well. Three better known mines in Kwangtung are Yangchiang, Shihjenchang, and Yaoling, probably all producing wolframite. Most Chinese tungsten ore entering the world market is medium high-grade wolframite analyzing 65% WO_3 plus. The small amounts of scheelite sold are of medium grade in impurities.

NONMETALS

Asbestos.—Although China's known asbestos consumption is still unaccountably small for a country rapidly gaining in industrial stature, demand for asbestos products should reach significant levels in the coming decade. China, in producing 150,000 to 200,000 tpy of good quality asbestos, has already become a moderate-sized world producer. The famous asbestos town of Shihmien (which means "asbestos" in Chinese) in Szechuan, with its reasonably up-to-date beneficiation mill, powerplant, and aerial tramway and an ore zone 4 miles long by a quarter of a mile wide containing very long-fiber chrysotile asbestos, dominated the country's asbestos scene. However, a second major asbestos deposit located at Penghsien near Shihmien no doubt will also become important.

Chinese asbestos deposits are found in a belt from Kirin and Liaoning Provinces to Southwest China (including Szechuan), passing through Hopeh, Shensi, and Inner Mongolia. Laiyuan in Hopeh Province and Chinhsien in Liaoning Province are leading producers of lower grade asbestos. No recent news has been available on the recently found Yuankiang deposit in Yunnan Province. China also has considerable amphibole asbestos.

Barite.—Chinese barite is coming to the forefront of mineral activity in view of the growing domestic market created by extensive drilling for oil and gas. Output in 1977 is estimated at possibly 300,000 tons (roughly 7% of the world total) and should continue to rise. Exports peaked at 125,000 tons in 1974. A recent offer to sell large tonnages of Chinese barite to the United States came to no avail. Chinese barite is produced in three grades—90%, 95%, and 97%.

Digitized by Google

China seems to have extensive barite resources, although current production areas are not known. Old deposits include Tangshan in Hopeh, Hwashan in Shantung, Hsuijen in Kwangsi, and Linchuan in Kiangsi. All barite deposits mentioned hitherto seem to have high-quality, easy-to-work ore bodies, with implications of initial reserves at millions of tons.

Cement.—China's cement industry continued to expand, with production exceeding 40 million tons in 1977. This ranked China fourth in the world, behind the Soviet Union, Japan, the United States, and just ahead of West Germany. More than half of the cement produced in the country, and perhaps as much as three-fifths, was furnished by small cement works, which reportedly raised output by about one-fifth over that of 1976,[21] as compared with 7% a year earlier. Apparently, large cement plants did not make too significant gains.

Little has been reported on the 30-odd large cement works (200,000 tpy or larger), which are scattered around in most of the industrial or population centers. Four plants are known to be rated at close to 1 million tpy, and a fifth one probably had recently been completed by the French. The earthquake-destroyed Tangshan cement works has not only been rebuilt but most likely expanded as well. The Talien (Dairen or Luta) plant in Liaoning Province no doubt had undergone modernization and expansion. An interesting news item concerns the Kwangchow cement works in Kwangtung Province,[22] with four rotary and two vertical kilns and formerly rated at 700,000 tpy. To correct its air pollution problem and to improve efficiency by recovering more fines and making byproduct potassium fertilizers, this plant was able to raise output by about 52,000 tpy and save 1,000 tpy of fine coal in the process. China also has 30 to 40 cement plants of 100,000 to 200,000 tpy. In view of its intention to accelerate industrial development, China probably will embark on a program to build more large plants (including suspension preheaters) both by their own efforts and with foreign help.

Nonetheless, the small-plant sector, which already has played a very significant role, probably will remain important in the scheme of things. China has well over 3,000 small cement plants of 3,000- to 5,000- and 10,000- to 50,000-ton sizes. The trend would be to eliminate the smallest ones and expand their larger counterparts whenever possible. Shantung Province with an output of nearly 3 million tpy leads China's Provinces in small-plant production, followed by Honan and then by Kwangtung, which possibly produces 1.5 million tpy. Small cement plants are in Provinces like Szechuan, Shansi, Hopeh, Hunan, Shensi, Kiangsu, Kiangsi, Liaoning, Kirin, Yunnan, Kweichow, Inner Mongolia, Sinkiang, and Tsighai. All told, China most likely has hundreds of cement plants producing tens of thousands of tons each. One such small plant, located in Pingshiang, Kiangsi Province, has been expanded to 100,000 tpy. As examples, 30,000-tpy-size plants have been recently built in Hsinglung County (two there) in Hopeh Province and Tungchuan County in Yunnan Province.

Diamond.—With more hard-rock exploration underway and the need to obtain more cores and samples even in oil and gas drilling, requirements for industrial diamonds have increased sharply in recent years. The best known diamond mine is located at Changte in the Province of Hunan. The exact location of a very important new diamond deposit in Liaoning Province is still not known. Unconfirmed reports indicate that natural deposits have also been discovered in Kweichow and Shantung Provinces. China has more than a dozen synthetic diamond plants, but the quality of the diamonds made does not appear to be totally satisfactory in grain size and strength. Nonetheless it was said that synthetic diamond bits have been successfully used to drill China's deepest producing oil and gas hole of 7,058 meters, in Szechuan.

Fertilizers (Mainly Nitrogenous).—Very significant progress was officially reported for fertilizer production in China during 1977.[23] The overall target for chemical fertilizers was achieved 21 days ahead of schedule, and output (probably combined gross tonnage) was said to be 31.9% higher than the historical peak attained in 1975 for the same period of time (presumably 344 days). Specific production gains for the first 11 months were 38.3% for synthetic ammonia, 42.7% for nitrogenous fertilizers, and 18.1% for phosphatic fertilizers.

Almost all the Provinces and special districts topped their 1976 production, including Shantung, Szechuan, Hopeh, Honan, Kweichow, and Shansi, which attained their quotas 34 to 72 days ahead of schedule. Shantung was the leading nitrogenous fertilizer-producing province with over 120 small plants and two large plants. Produc-

Digitized by Google

tion increases were noted for each of the quarters of 1977. It was admitted that the original targets for 1977, as projected in 1974, were not quite fulfilled. Nonetheless, output levels were significant by world standards. Plans being implemented and construction already underway would roughly double Chinese production within 3 years. Moreover, the Chinese are expanding indigenous production across the board (with considerable stress on smaller plants), and apparently asking for bids for additional large foreign plants (unconfirmed). Although nitrogenous fertilizers are of primary importance, phosphate development is progressing rapidly, and there are clear signs that potassium fertilizers will be carefully investigated as well.

China probably produced close to 4 million tons of contained nitrogen (N) in 1977. Not counting the 13 new large foreign plants purchased in 1973, all to be placed in operations by 1979, China still has about a dozen other sizable nitrogenous fertilizer plants and over 1,200 small- and medium-sized nitrogenous plants scattered around the country; during 1975 the latter smaller plants reportedly produced over half of the country's total output of synthetic ammonia. A typical small plant produces 3,000 to 5,000 tpy of aqueous ammonia or ammonium bicarbonate, and medium-sized plants may produce 50,000 to 100,000 tpy. China built its first 200,000-tpy-size reactor for urea production at the Harbin Boiler Works in late 1977.[24]

Of the 13 complexes or "whole plants" purchased, 8 are being handled directly by Pullman-Kellogg Co. and its Dutch subsidiary. The 1,000-tpy-ammonia units are based upon Kellogg's own process, while the 1,620-tpy-urea units are based upon the Stamicarbon stripping process. Two other plants with nearly similar size units and having Kellogg ammonia equipment have been completed by Mitsui-Toyo Engineering, location unknown. The remaining three facilities were awarded to the French-owned Heurtey Industries, with units based upon the Haldor Topsoe ammonia process and the Stamicarbon urea process. Heurtey's plants are located at Nanking west of Shanghai, Canton (Kwangchow) near Hong Kong, and Anching 700 kilometers upstream on the Yangtze River from Shanghai. The eight Kellog plants are located in the Provinces of Heilungkiang (at Wolitun within the Taching oilfield), Szechuan (near Luchow within the gasfields), Hopeh (near Chengchow), Liaoning (at Panchin near Shenyang), Yunnan (possibly near Kunming), Hunan, Hupeh, and Kweichow. The 13 plants all told can produce a total of nearly 7 million tons of urea equivalent or 3.4 million tons of contained nitrogen. It has been rumored that the Chinese were asking Kellogg to bid on 11 new coal-fired ammonia plants.

Specific news has been available on some of the larger plants. The Heurtey plant in Kwangchow within a petrochemical complex was capable of producing 1.4 million tpy of various nitrogenous fertilizers, as of mid-1977. The Taching Kellogg plant[25] in Keilungkiang and the Luchow Kellogg plant in Szechuan, both also within petrochemical complexes and rated at more than 1 million tpy of finished products each, went through their first major overhauls late in the year. The Kellogg plant in Hopeh is of the same size as the two above and was also placed in operation during 1977. The fourth and latest (February 1978) Kellogg plant to go onstream was the one in Yunnan which probably uses natural gas piped in from Szechuan. The Peking oil refinery and petrochemical complex also has a large nitrogenous fertilizer plant. Two other fairly large plants have been newly completed—one in Hochih in Kwangsi Province and one in Ulashan in Inner Mongolia.

Despite efforts to increase production, China continued to be by far the largest importer of nitrogenous fertilizers in the world. The tonnage purchased for delivery in the second half of 1977 were as follows:[26] Urea—Japan 542,000, Nitrex 250,000, Indonesia 100,000, Iraq 100,000, and Kuwait 100,000; compounds—Complexport 300,000, Spain 50,000, and Greece 40,000; ammonium sulfate from Japan 150,000; and ammonium chloride from Japan 270,000 tons. For 1977 as a whole, Japan exported 926,477 tons of urea, 631,800 tons of ammonium sulfate, and 348,900 tons of ammonium chloride to China.

Fluorspar.—China has been an important producer and exporter of fluorspar for several decades, and output in 1977 probably exceeded 350,000 metric tons. A large surplus has been traditionally exported, mainly to Japan, which took 117,115 metric tons in 1976 and 111,147 tons in 1977. However, Japan's overall steelmaking requirements for fluorspar continued to decline on a per-ton-of-steel basis, and its steel industry prefers Kenya metspar to the lower grade Chinese metspar. The U.S.S.R.

Digitized by Google

took 84,840 tons in 1974 and 55,047 tons in 1975 (no later reporting of this nature by the Soviets). Poland generally imports 10,000 to 15,000 tons of Chinese fluorspar annually. Most fluorspar is metallurgical grade, but a significant share of the output is acidspar. Very high-grade lump fluorspar was trial shipped to the U.S. market in mid-1976, but high shipping costs and duty ($8.40 per long ton for metspar and $2.10 for acidspar) here illustrate the difficulty of selling in distant markets. Up to 100,000 tons of fluorspar were consumed in China during 1977, including at least 50,000 tons by the steel industry and 20,000 tons by the aluminum industry. China was becoming interested in hydrofluoric acid. China's annual fluorspar demand should reach the 200,000-ton level within a decade.

Historically, the leading producing districts have been Wuyi in Chekiang Province, Kaiping in Liaoning Province, and Lung-hua in Jehol Province. Fluorspar has also been mined in Shantung and Kwangtung Provinces. A new producer has come into prominence in recent years, namely the Taoling mine in Hunan Province, which is also a lead-zinc producer. Taoling has flotation cells and probably produces over 80,000 tons of acid-grade fluorspar annually. Another recently developed fluorspar producer is located in Pecheng County, Fukien Province. Fluorspar might well be found in many tin-barren granite ranges in China, if carefully explored.

Phosphates.—China's phosphate deposits seem to be widespread in the eastern third of the country. Reserves undoubtedly are large, and the Chinese are making good use of the uneven and often poor-grade ores. Earlier discoveries were mostly near the Burma border, particularly the Kunming and Kunyang areas of Yunnan Province, although a big high-grade phosphate rock deposit was found in Yunnan in 1977. More recently, workable deposits were also found and worked in the Kaiyang region of Kweichow, the Tau River area of Szechuan, the Foshan area of Kwangtung, the Liuyang-Huachiao area of Hunan, the Chinghsiang area of Hupeh, and the Chaoyanglin area of Kiangsi. There seem to be sizable mines in Kweichow, Hupeh, and Kiangsi Provinces. Shantung Province with its many small mines has emerged as the leading producer of phosphates during the last few years. Very recently, a sizable deposit of phosphate rock was discovered in the North China Province of Hopeh around Fanshan. Reportedly, a phosphate shale mine has started operations in Northeast China's Kirin Province within the county of Changpai. By raising annual production of phosphate rock to possibly 4 million tons, China has cut down on imports from countries like Morocco and Vietnam to very small tonnages from 2 million tpy several years ago.

China's small phosphate plants, which may total over 1,500 in number, account for as much as three-quarters of the country's output of chemical phosphates. Shantung has nearly a third of these plants. In order to supply the necessary raw materials, about 150 phosphate rock and sulfur mines spread out in 59 counties[27] had been built in Shantung as of May 1977 and 90 more had been designed or were under construction. Since 1975 alone, the Shantung Geological Survey had located over 300 phosphate sites and 37 pyrite sites within the Province. Kwangtung Province claims two dozen small phosphate fertilizer plants, capable of producing a total of more than one-half million tons of compound fertilizers. Relatively large superphosphate plants that have been mentioned in the press include Nanking, Changsha in Hunan, Hunghochou in Yunnan, Shanghai, Taiyuan in Shansi, Kwangchow and Chanchiang in Kwangtung, and Yingtan and Tunghsiang in Kiangsi. The Chinese have started to use spent shales, cement plant wastes, slags, and boiler ashes for fertilizer raw materials.

Potash.—China has not yet examined its potash resources to any great extent and does not use much of this fertilizer ingredient. Thus, production and imports are both low, and there is no indication that any sizable natural potash deposit has been found so far. However, interest is growing, judging from the fact that potash is being recovered from saline operations, sedimentary rocks, and various waste materials. While it is too early to estimate tonnages, sea salt works at various locations such as Tangku near Tientsin and Luta in Liaoning and brine works in the Tzukung (or Tzuliuching) area of Szechuan are known to recover potassium chloride.

The first important mention of potash in the Chinese press was in connection with the Chaerha salt lake works in the Tsaidam Basin, where reportedly a new technique was developed to recover byproduct potash; as a result, output of this plant was raised twentyfold in the decade ending 1976. The

Digitized by Google

Shantung Geological Survey was prospecting for potash along with phosphates and pyrites. Apparently, potash occurs at depth and this makes it difficult for small-scale operations. Shantung's geologists, however, incidentally found a sizable zeolite deposit which may be useful in recovering potash from seawater.[28] The large Kwangchow cement works started to recover more kiln dust, which was converted to potassium fertilizers. Elsewhere in Kwangtung Province, about 27 plants were capable of producing 150,000 tons of potassium calcium fertilizers annually and 24 other plants were capable of producing 600,000 tons of phosphate-potash fertilizers.[29] Small potash and phosphate plants were also operating in Szechuan Province, and certain coal-fired thermal plants were making byproduct fertilizers from the ashes.

Pyrites.—China has been an important world producer of pyrites for some time and annual output is at least 2 million tons. Previously known are two large pyrite mines—Hsiangshan in Anhwei and Yingte in Kwangtung. Also, pyrite in Szechuan Province has been made into sulfur, and sizable tonnages of pyrite are being mined in Shantung Province. Late in 1977, a selenium-bearing, probably cupriferrous-pyrite mine was reportedly found somewhere in Kwangtung Province.[30] In early 1978 it was reported that China's largest pyrite mine was being built in the Yunfu area of Kwangtung; construction at this open pit mine had already been half completed, including facilities like railroad, docks, water reservoir, and powerplant.[31]

Salt.—China in producing an estimated 35 million metric tons of plain salt in 1977 was approaching the production level of the United States, the world's largest producer. However, unlike the United States, where most of the salt produced is rock or brine salt, China extracts 80% to 90% of its edible salt by solar evaporation in wind-protected shallow bay areas along the coast. A large part of Chinese salt is for food purposes, but a growing proportion is being consumed for industrial purpose. It was claimed that China's 1977 salt target was fulfilled 110 days ahead of schedule, that the tonnage was a historical record, and that the general quality was excellent and production costs low.[32] The Tangku salt field, after the salt pans damaged by the Tangshan earthquake were quickly repaired, reportedly overfulfilled its 1977 output quota. Kwangtung Province apparently produced 75% more salt in the first 9 months of 1977 than during the same period a year earlier; its largest fields Yinkou and Hainan Island both attained their full year's targets near the half-year mark. Shantung, another important sea salt-producing Province, established a production record. Kwangsi Province also met its 1977 goal and produced at record levels despite inundation difficulties.

Inland, Szechuan Province with its famous salt brines (and natural gas to evaporate the brines) from the Tzuliuching area produces just over 5% of China's salt. Kiangsi Province has a sizable rock salt mine and salt works at Chingkangshan. Ninghsia Province has developed an inland salt field called Chilantai. Sinkiang with its biggest saltworks at Chichiaching in Hami District now produces enough salt for its 15 million people. China has hardly touched the large potential salt resources associated with the oil and gas fields. Various areas described below produce plain salt along with other salts.

China's production of other kinds of industrial salts has also made significant progress, along with basic investigations as to their origin, availability, and extraction problems. The Tsinghai (Chinghai) Salt Lake Institute of the Chinese Academy of Sciences has recently completed a survey of more than a thousand salt lakes in the Tsinghai-Tibet Plateau which together represent half the dry, semidry, and salty lakes in the entire country.[33] Two important scientific books were published on this general subject. One is entitled "Salt Lakes of the Tsaidam Basin," which provides good scientific guidelines to exploration for new saline sedimentary beds. The second is called "Methods for Analyzing Brine and Salts," which evaluates the chemical and physical properties of the pertinent minerals and elements.

Reportedly, a new process was devised for extracting carnallite from the Chaerhan Salt Lake in the Tsaidam Basin, based upon the "daily salt separation (crystallization) quota." A new technique for making potassium fertilizer was also developed at the Chaerhan works, which enabled potassium fertilizer output to increase twentyfold during 1966-76. Moreover, a method to extract boric acid directly from the borates obtained from Chaerhan's mixed salts, through the use of sulfur dioxide, was introduced.

A description of the over-three-thousand-year-old Yuncheng inland salt field (semi-

Digitized by Google

dry lake deposit), located in the southwestern part of Shansi Province, appeared in the press.[34] This salt field is 20 to 30 kilometers long and 3 to 5 kilometers wide. It is a complex salts storehouse, much like Searles Lake in California. Aside from large tonnages of sodium sulfate, sodium chloride (edible salt), magnesium sulfate, and calcium sulfate (gypsum), there are many kinds of lesser minerals and elements such as bromine, iodine, potassium (potash), borates, lithium, and many "rare" elements. Whereas only edible salt was produced historically, Yuncheng has now been modernized into a chemical raw material base with sodium sulfate as the foremost product. The degree of mechanization has steadily increased, output has been continually expanded, and a greater variety of products has been manufactured, including dehydrated sodium sulfate, sodium chloride, sodium silicate, and bromides, etc.

A large deposit of high-grade natural soda reportedly has been found in Tungpai County of Honan Province, within the Paleogene system of Cenozoic rocks. Previously, such minerals were found only in saline lakes of the Quaternary era.[35]

MINERAL FUELS

Coal.—The Chinese have informed certain foreign visitors that their 1976 coal output was in excess of 480 million tons; also, it was suggested that the production in 1977 was about 10% higher. Thus, China's total 1977 output of marketable coal can be conservatively estimated at 500 million metric tons. Specific claims for 1977 noted that the national target for raw coal production had been achieved 28 days ahead of schedule (output increase was 10.2% compared with the same period last year); target for the key or major coal mines, 12 days ahead of schedule (output increase was 8% compared with the same period last year); national target for washed coal, 25 days ahead of schedule; and the geological prospecting plan, 51 days ahead of schedule.[36] An important National Conference of Coal Mining and Tunneling Teams took place in November 1976, followed by another National Conference in January 1977 which Chairman Hua Kuo-Feng himself attended. A western article described China's "grand plan for coal" and the status of coal extraction practice and equipment there.[37]

Many existing mines and combines reported great increases in extraction rates in 1977, no doubt in part compensating for the relatively low output levels a year earlier when political difficulties hampered operations.

Fifty pairs of large coal shafts were completed in 1975, and 42 pairs of large coal shafts were placed in operation in 1977.[38] The Chinese started to use considerable "stone coal" (bone or shale coal) for power generation.

Coal production in Chiangnan (which means south of the Yangtze River and embraces the Provinces of Kiangsu, Chekiang, Anhwei, Kiangsi, Fukien Hunan, Hupeh, Kwangtung, and Kwangsi) continued to increase, perhaps to about 140 million metric tons. The degree of self-sufficiency in coal of this area had risen to more than 70%, which means that proportionately less coal needed to be shipped from the north. The Chiangnan coalfields basically have been developed since 1965 when there was only one large combine—Huainan in Anhwei, which is the leading coal-producing Province of the south. Now, there is a second large coal combine in Anhwei, namely Huaipei, which has not yet reached full production. Combined output of Huainan and Huaipei was well over 20 million tons of marketable coal in 1977. Recently, a third large coalfield, called Linhuan, was discovered in Anhwei, Su Hsien, reportedly with three times the reserves of Huaipei.[39] Apparently the country's small- and medium-sized mines provided about a fourth of the national output in 1977. Many of these mines are down south, but there is also tributary output of small mines in the north, as is the case of Shansi Province.

Kailan combine's 1977 raw coal output was approximately half of the peak level of 25 million tons achieved in 1975, although it was claimed at yearend 1977 that pre-quake daily production rates had been reestablished. Aside from pumping out 160,000,000 tons of water and rebuilding all shafts at Kailan's seven mines, about 370 kilometers of roadways were restored, a hundred-odd coal working faces were developed for production, and over 33,000 units of equipment were rebuilt.[40] The Luchiatun colliery was the first to be fully operative and its 1977 output was brought up to more than 2.5 million tons. The Chaokochuang colliery was aiming at similar tonnage for the year, and topped the 20,000-ton-per-day (tpd) level in mid-December. At the Linhsi colliery, all of the 80-odd "integrated mechanized hydraulic support systems" were brought back into production. The Fankochuang colliery,

Digitized by Google

with six coal seams and many kinds of working conditions, was made into one of China's most mechanized coal mines with output capacity brought up to about 4 million tpy. The best coal brigade at Fankochuang established a national output record of nearly three-quarters of a million tons of coal per year. Kailan produces at least 3 million tons of coal annually by hydraulic mining methods.

Shansi Province, which is virtually underlain by coal and producing about a sixth of China's total coal, continued to do well in its effort to expand output severalfold in the next decade or two. Even the small mines in the Province have come into prominence; during the first 9 months of 1977, combined output of Shansi's small mines reportedly totaled 24 million tons.

Shansi's two leading producers were Tatung and Yangchuan. At the Tatung combine, which has 13 collieries, production in 1976 was reported at 18 million tons of marketable coal[41] and projected production in 1977 was 21 million tons. Westerners have visited at least three of its collieries. The new Chinhuakung colliery near the city of Tatung may have a half billion tons of reserves of low-ash, low-sulfur, high-heat-value bituminous coal (including coking coal) which is produced at about 2.5 million tpy and shipped to north China markets as far as Peking. The nearby 50-year-old Meiyu underground mine also has about half billion tons of reserves and covers 15 square kilometers. With 10 gently dipping seams of 1- to 10-meter thickness, Meiyu's 1977 output was about 1.8 million tons of 10% ash (before cleaning) steam coal. The Yunkang colliery, although 35 kilometers northwest of the Meiyu mine in the same coalfield and also under the Tatung combine, produced about 2.5 million tons of steam and blending coals in 1977 with plans to more than double this within a decade. The Yunkang mine covers an area of 80 square kilometers, has 13 coal seams (2 seams now worked are 4 and 6 meters thick), and mines from shafts now about 200 meters deep. The Yangchuan combine in Shansi is China's largest anthracite producer, and output in 1977 apparently was over 13 million tons. Yangchuan collieries are highly gaseous.

Coal production in Liaoning Province remained relatively stable; the Province provided about 12% of the national output and maintained its second ranking position after Shansi. Fushun's two open pits and three underground collieries together produced 12 to 14 million tons of marketable steam and blending coals in 1977, from gently dipping and very thick coal seams overlain by oil shale. Specifically, the Fushun West open pit mine produces about 4.5 million tons of cleaned coal annually, and the Lau Hu Tai underground mine, 3.5 million tons. Liaoning's other large coal combine Fuhsin maintained output at about 18 million tpy. A few interesting statistics were mentioned for Heilungkiang's large coal combines. The Hokang combine produced a record 63,000 tons of raw coal on May 1, 1977, but the average for the year was probably less than 50,000 tpy. The Chihsi combine produced in excess of a million tons monthly in the spring of 1977, and the Shuangyashan combine increased output every month during the first half of the year. Shensi Province's Tungchuan combine reported output at 6 to 7 million tons in 1977. China's first combined coal-natural gas operation, at the Shih-Chieh mine in Shansi, came onstream.[42] In Shantung Province, Tzupo combine's output was reported at 5.8 million tons in 1976, and Tsaschuang combine reportedly established a daily output record of 31,000 tons in August 1977 (about 17,000 tpd in May 1977).[43]

The fairly new Pintingshan combine in Honan Province and its coking coal was in the news again. Production was in shambles in 1976, according to Chinese official reports, because of the "gang of four." Pingtinshan has about a dozen collieries; its Kaochuang or No. 4 mine and its No. 10 mine had been classified as "advanced large collieries," and its No. 1 mine had been rated at 1.5 million tpy. A report in late 1977 indicated that Pingtingshan's 1975 output was more than 10 million metric tons (possibly raw coal) and that output during March-September 1977 had exceeded 1 million tons for every month.[44] Thus, management difficulties had been overcome, and production brought up to record levels, so as to meet the growing needs of the steel and other industries in north-central China.

The Wuta combine (also called Holanshan) in Ninghsia was again reported in literature.[45] It is located on the railroad west of Paotou and north of Yinchuan. Holanshan embraces four coalfields in an area of 50 kilometers, and has eight pairs of shafts, an open pit mine, a large coal washing plant, and many auxiliary facilities serving steel and other industries in the northwest. Although Wuta has 20 years of

Digitized by Google

history, the surge in output came in 1975. Production in 1976 was said to be 23% higher than in 1975, and production in the first half of 1977 went up another 16% compared with the same period in 1976. Overall output in Ninghsia Province probably was at least 8 million tons, and most of this came from the Wuta combine.

Szechuan Province in the southwest, noted for agriculture, bamboos, pandas, natural gas, and brine salt, has uncovered a large iron deposit and was building up its coal production. The Province probably produced about 15 million metric tons of bituminous coal in 1977, registering at least a 20% increase over that of 1976. The premiere combine is Paoting in rugged terrain near the Yunnan border where there are seven collieres, a cleaning plant and other industrial facilities, producing medium-volatile coking coal. There are many other smaller coal mining enterprises, including Yungjung, Fujung, Jungshan, and Chiayang. Except for Paoting, Szechuan coal mines are relatively small, although there are many seams to work.

Petroleum and Natural Gas.—China's oil production was between 90 and 100 million metric tons (or 2 million barrels per day) in 1977. The official line was that the increase was about 8% over that of 1976, compared with an increase of 13% in 1976 over that of 1975. Taching and No. 1 oilfield Shengli did very well, but the No. 4 oilfield Takang apparently faltered because of the earthquakes in the second half of 1976. Little was said about the new Panshan oilfield near Chinchow and Yingkou. However, there seemed to be great enthusiasm over a fifth large oilfield, a newly reported one south of Peking called Huapei or north China oilfield, where high-yield wells and sharp increases in output were claimed. The old northern Sinkiang field continued to make progress and a new southwestern Sinkiang field apparently has been uncovered. Nearby, there was also great activity in Tsinghai Province.

China already ranks about tenth as a world oil producer, and prospects of doubling output by the latter part of the 1980's are excellent. Further growth to beyond 200 million tpy would be rather conjectural on the basis of present knowledge. However, the reserve situation (particularly onshore but also offshore) seems good when compared with the major oil producers in the world outside of Saudi Arabia. One report indicates that Vice Premier Teng Hsiao-Ping told Japanese Parliament members in late 1977 that the new estimate of Chinese oil reserves is 400 billion barrels (7.4 barrels equal one metric ton).[46] China's oil industry was clearly moving upward, with additional reserves found in existing oilfields, reports of completely new oilfields, and indications that petroleum also occurs in older and deeper Paleozoic rocks. At Taching, very important reserves have been located at greater depths and around the fringes of the present oilfield. At Shengli, extensive reservoirs and structures have been discovered at 3,000 meters and deeper. The Huapei oilfield has just started normal operations and Supei to its southeast also shows good promise. Not too much exploration work has been done in Sinkiang and Tsinghai as yet. As noted below, offshore exploration is gaining momentum.

The Chinese have sent many oil and gas delegations abroad. Probably the most interesting and high-level one came to the United States in January 1978, headed by the president of the China Petroleum and Natural Gas Corp. An American oil drilling equipment mission was in China in the late summer of 1977, followed by a technical mission of U.S. oil executives later in November. All signs point to the fact that China has already found extensive oil reserves, expects to discover even more, hopes to sell larger quantities of petroleum abroad, wants to learn from oil producers around the world and particularly from the West, intends to buy considerable equipment and technology to explore for (especially offshore) and refine oil, and with the proceeds from oil exports, plans to purchase foreign metal supplies, machinery, plants, and know-how for industrial development in general.

While the Chinese have never shown any interest in joint ventures and appear to be only remotely inclined to accept the concept of work contracts, they apparently were ready to make a deal with the French in November 1977 that would represent a breakthrough in their commercial arrangements.[47] In negotiating to buy $250 million worth of French oil drilling technology and equipment (possibly for the development of the new Nanhai oilfield near Canton), which the West hopes would be the beginning of a new wave of Chinese buying, the Chinese may agree to accept financing by the French state-owned Banque Nationale de Paris for the purchase. Hitherto, loans have not been accepted by the Chi-

Digitized by Google

nese, although time deposits have been previously arranged with the Japanese.

While concentrating on their own technical resources for exploration onshore (they are, however, interested in U.S. oil-prospecting data analysis computers), the Chinese were looking more into foreign equipment and know-how for offshore operations. Generally, they feel that over 40% of China's land area and half that much Continental Shelf area have potentially oil- and gas-bearing sedimentary rocks conducive to oil search. Peking indicates that it might have started offshore drilling around the Spratley Islands of the controversial South China Sea. As of yearend 1977, China was operating three foreign-built rigs offshore, had a fourth on order, and finally purchased a fifth.[48]

In the early stages of offshore operations, concrete and earthen dikes were built a mile into the Gulf of Pohai. By the late 1960's, a number of four-legged fixed platforms were installed. In 1972, a Fuji rig was put to use and in 1973, China built its catamaran drillship called "Kantan I." Subsequently, Singapore's Robin Loh built and sold two Rabray 300 jack-up rigs for the Chinese after fitting them with Houston ETA Engineering's equipment; their Hitachi partners in Japan filled a third order. These roughly $20 million rigs (with U.S. equipment on board worth another $10 to $15 million each) operate in 300 feet of water and have 25,000 feet drilling capability. One of these ran into technical trouble while working 50 miles off Pakhoi (Peihai) in the Gulf of Tonkin and foreign experts had to be flown in to make repairs. In the summer of 1977, the Norwegian-owned Borrgny-Dolphin, which had operated in the North Sea, was bought for $27 to $40 million. This latter semisubmersible rig can work at 600 feet (1,000 feet if modified) and probably will be used near Hainan Islands. In November 1977, the Texas-based National Supply Co. sold two self-contained drilling rigs to the Chinese for a total of $20 to $30 million.

The Chinese exported considerably less oil in 1976 and 1977 than they had hoped. However, exports totaled very possibly 10 to 11 million metric tons in 1977, including roughly 6.5 million tons to Japan, over a million tons to North Korea (pipeline there has capacity of 1.5 million tpy), 900,000 tons to the Philippines, 700,000 tons (products) to Hong Kong, 500,000 tons to Romania (barter agreement for Romanian fertilizers), and up to a half million tons to Thailand. Cambodia was said to have imported 600,000 tons of Chinese oil products in 1975. Singapore may be taking some Chinese oil to pay for Chinese purchases there.

The Sino-Japanese long-term agreement for Chinese oil was practically firmed up by January 1978. Japan will take 47 million tons of crude oil during 1978-82, with 6.8 million tons programed for 1978 and 15 million tons for 1982. The coal part of the deal involving about 5 million tpy exports to Japan evidently has not yet been finalized. Japan is thinking about installing its first heavy oil cracking facilities to treat heavy Chinese crude by 1981, after which time some Japanese observers believe that crude imports from China can go as high as 20 to 30 million tpy. Crude from Shengli and Huapei oilfields were being sent to Japan for testing at yearend 1977, indicating the likelihood of shipping commercial quantities of these crudes there in addition to Taching crude. North China crudes are lighter but more salty than Taching crude, and higher in sulfur. Taching crude is more waxy than Indonesia's Minas crude but has less nitrogen. Shengli crude now goes to the Philippines, where Caltex and other companies are gearing up on anticorrosion facilities. Caltex shipped 45,000 tons of Taching crude to Sydney's Kurell refinery in 1976, and has arranged to ship 100,000 tons of Taching crude to its Japanese affiliate Nippon Oil. The possibility of more Chinese crude going to Japan worries some refiners there.

The Taching oilfield, near Harbin and only 180 miles from the Soviet border, apparently produced 40 to 45 million metric tons of crude oil in 1977. Its target for that year reportedly was fulfilled by December 26, and actual output was said to have been the highest in history, possibly even more than the 45 million tons mentioned above. There were indications that Taching was holding down output by shutting off wells, because of the weak domestic and international demand for its oil. There were two major announcements concerning exploration—at greater depths and around the perimeters of the oilfield known to cover at least 150,000 square kilometers. The management of Taching was extremely confident that oil reservoirs (at 3,000- to 4,000-meter depth) under the presently known ones (average depth about 1,000 meters) have as much reserves as the shallow reservoirs.[49] Four exploratory holes

Digitized by Google

have been drilled to about 3,000 meters, with the expectation of locating commercial structures by the spring of 1978. A simultaneous thrust was to develop oil in a new region in the southern part of the oilfield.

Thus Taching, possibly one of the world's 10 leading oilfields, holds good promise for the future and probably has not peaked at all. Operators at this field indicate that reservoir pressures have been generally steady, most wells still maintain their natural flows, production remains at high levels, and new techniques of fracturing and water injection have been successfully applied. Taching's refinery remains at about 6 million tpy, but the petrochemical complex has been made more sophisticated. There are now two large foreign designed chemical fertilizer plants (American and Dutch), one or both rated at about a million tons of finished fertilizers per year.

The Shengli oilfield, located at the mouth of the Yellow River and covering 80 (east-west) by 120 kilometers (north-south), is hopefully being built up to another Taching. It has about 100,000 workers, roughly the same as Taching. Output in 1976 for Shengli was close to 18 million metric tons, and the tonnage in 1977 was probably higher. A number of high-yield oil wells were drilled (to about 3,000 meters) and placed in operation during 1977, to supplement the existing producing wells mostly 1,000 to 2,500 meters deep.[50] Geological exploration verified that similar deep and faulted formations exist widely in the area. Drilling and construction were proceeding rapidly in the new oil area, and additional roads and pipelines (two important ones at present are to Tsingtao and Tzupo) were being built. Management at Shengli claimed very efficient drilling with artificial diamond drag bits (in place of alloy drag bits) for deep holes and a high-pressure jet-drilling technique. Reportedly, new "chain" pumps were also effective. There has been no additional news on the scheme to alter the course of the Yellow River, designed to facilitate oil extraction.

Shengli is rather integrated, possessing additional facilities like two fertilizer plants, two refineries totaling 6 million tons in annual capacity, a synthetic rubber plant, and a petroleum institute. Overall, Shengli's capacity will be increased considerably in the next few years; its current output is less than half that of Taching's. Additional markets were being sought for Shengli's heavy and salty oil.

The Kwangchow petrochemical works near Hong Kong received its first shipment of Shengli crude in August 1977. About 900,000 tons of this crude also went to the Philippines in 1977, with the expectation that much larger tonnages will be shipped there; Caltex, the leading importer in that country, was planning to install more anti-corrosion equipment in its refinery to cope with Shengli oil. Samples of Shengli oil were being sent to Japan, in anticipation of sizable exports there.

There has been very little news about the Takang oilfield near Tientsin and earthquake-ridden Tangshan, often mentioned as China's No. 3 oilfield. Takang reportedly resumed normal operations shortly after the Tangshan earthquake in late July 1976. However, things may not have been running too smoothly and certainly Takang's expansion plans might well have been delayed. Also, Tientsin and Peking, which have been markets for Takang's oil and gas, went through additional earthquakes late in 1976 and these quakes apparently did slow down Takang. Thus, it would not be surprising if Takang's 1977 production dropped below 10 million tons. Another new large oilfield in Pohai Bay and northeast of Takang, which can be designated as Yingkow-Chinchou or Panshan, also has not been mentioned much in the press during 1977. The Panshan field, which is on land but very possibly extends into the bay, was not affected by earthquakes at all. It was apparently still being developed, although output no doubt has already surpassed the 5-million-tpy level.

Another large new oilfield came to light in 1977, which can be designated as Huapei or Jenchiu. It covers a large area that has not yet been carefully delineated. Centered in Jenchiu county southeast of Paoting in Hopeh Province, it is known to cover four counties extending from almost Peking south to the Shanghai railroad. Various thousand-ton-per-day wells have already been developed in the Kuchien Mountain area.[51] In developing this field, Paleozoic rock was found in an oil-bearing structure, which was named Kuchienshan formation. To Chinese oil geologists, this means that exploration should not cease upon passing through younger formations and that Huapei (means North China) and other areas in the country could have much additional oil potential, in view of the widespread nature of Paleozoic rocks. Oil production in this field no doubt has been increasing sharply

Digitized by Google

and samples have been shipped to Japan in the hope of future sales there. The Chinese also feel most hopeful that another large field will be developed farther south and east in southern Shantung and northern Kiangsu; this field has been designated as Supei (meaning Kiangsu North).

The Karamai or Kolamai oilfield located in western Dzungarian Basin in Sinkiang Province was again cited for good performance in 1977 which implies that overall output may have surpassed 7 million tons. This oilfield was being streamlined in recent years, along with the development of a new sub-field and construction of more refining facilities. Much exploration has also taken place in the Tarim Basin (Takla Makan) in southwestern Sinkiang and apparently good reserves have been found. China's oldest oilfield, Yumen in Kansu Province, probably produced 3 to 4 million tons of crude oil in 1977, after its seventh year of "rejuvenated" good performance based upon discovery of additional reserves at deeper reservoirs. Yumen has a local refinery and sends oil by pipeline to the Lanchow refinery as well.

Development of the Tsaidam Basin in Tsinghai Province has moved ahead, although production particulars are not known.[52] "Derricks in Tsaidam are lined up like forests," and about two hundred highways have been built in "this land of minority people." By September Tsinghai's 1977 drilling plan reportedly had been 89% fulfilled, and the crude oil output target, 87% fulfilled. Several oilfields have been reported for western Kirin Province in northeast China, that is, Chiling, Hungkang, and Hsimu); developed in the last decade, at least one of these fields is said to be relatively large and stable in yield. Little is known about the exploration offshore in the Nanhai area south of Canton.

China's natural gas production is moving up sharply, registering about a 22% increase over that of 1976 compared with a growth of 11% a year earlier. Output in 1977 may have reached 95 billion cubic meters, one-sixth of U.S. production and a fourth of U.S.S.R. production. Szechuan Province has long been famous for natural gas itself, although increasing quantities of oil are produced also. At yearend 1977, China contracted to buy a $20 million natural gas clearing plant (to remove oil, sulfur, and water) from Chiyoda Kako of Japan, presumably for use in Szechuan. Production of gas in Szechuan has gone up fivefold since the Cultural Revolution.[53] Several hundred gas-oil structures have been found in the last few years. Methods have been devised to produce gas from high-pressure wells and work sour gas. Strong artificial diamond drill bits and special tungsten carbide bits have been made and used in drilling holes that are mostly more than 4,000 meters deep. Szechuan's and China's deepest well was 7,058 meters, as of July 1977.

In Szechuan, gas is used to run most of the fertilizer plants, powerplants, steel plants, salt facilities, and many cement plants as well. This gas is also being sent to southeast China via pipeline which apparently has already reached Changsha. Szechuan has about a hundred small and several large fertilizer plants that use gas. Natural gas is also associated with most of the leading oilfields. Eventually, the Chinese hope to sell liquefied natural gas (LNG) from Takang to Japan. Takang's gas already goes to Tientsin and Peking.

China's largest shale oil operation is now Maoming (Mowming) located in Kwangtung Province. Its overall prominence, however, is due mainly to the recent installation of a regular oil refinery and a 140-kilometer pipeline from Chanchiang to bring outside crude in, including Iranian crude oil. Maoming's shale oil operation produces by-products like cement and rare minerals and metals. It is known that there are also six shale oil retorting plants which together may be producing 1 to 1.5 million tpy of shale oil. One report states that Maoming's shale oil production and crude oil production both increased about threefold during the decade ending 1975. It has a new lubricants plant and five new "installations for removing and producing sulfur."[54] Reportedly, Maoming fulfilled 1977 industrial production targets 1 month ahead of time, and its gross industrial output was 14% higher than a year before. Output of refined oil products at Maoming was roughly 11% higher than in 1976. China's second and oldest shale oil operation Fushun in Liaoning Province continued to diminish in importance because of natural oil coming from Taching and less local oil shales mined at the open pit coal mines. There seem to be nine batteries of oil shale retorts that together could produce 1 to 1.5 million tons of shale oil yearly. Probably less than half of the facilities are now worked, and the 1977 output might have been as low as 600,000 to 800,000 tons of retorted oil. China's effort to

Digitized by Google

build pipelines, ports, and vessels to ship oil and gas (and eventually perhaps also coal dispersed in oil) continued to make steady progress. Apparently, there are just over 5,000 kilometers of trunk pipelines in the country at present (excluding local gas pipelines in Szechuan totaling well over 1,000 kilometers). One of the longest pipelines is from the Taching oilfield via Tiehling and Chinhuangtao to Peking. Taching oil is also piped to Talien and North Korea. Another long pipeline is from Szechuan to the east coast around the oil and gas fields. Purchase and manufacture of pipe obviously have high priority.

When the oil reaches ports, China has the problem of moving it to domestic and foreign markets. In recent years up to 50 deepwater berths have been built from north to south in Talien, Chinhuangtao, Tientsin, Yentai, Tsingtao, Lienyunkang, Shanghai, Whampoa, and Chanchiang. Talien's Hsinkang Harbor can accommodate a 100,000-dwt (deadweight ton) tanker and 50,000-dwt tanker simultaneously. Another new completion was the Huangtao port in Tsingtao Harbor which can now handle a 50,000-dwt tanker and a 20,000-dwt tanker simultaneously. Changchiang can also berth 50,000-dwt ships. However, most berths in China can only handle 10,000-dwt to 30,000-dwt tankers, although many can load and unload coal also. The country's tanker fleet has been built up to about a million tons, two-thirds comprising of about 20 vessels purchased from Scandinavia, the largest of which is the 89,200-dwt Josephine. The maximum-size Chinese-built tanker is 50,000-dwt, and the first of four is called Hsihu. China's present fleet can only handle about 3 to 4 million tons of annual oil exports. Apparently, Chinese thinking is to handle half of future oil exports with tankers built domestically and purchased.

China's oil refining and petrochemical facilities were being expanded at a pace commensurate with the increase in crude production. Judging from exports and the extent of direct burning of crude, it appears that the country's refining capacity has reached about 80 million metric tons per year. Chinese refineries are basically of two types—an "Esso" type of about 2.5 million tpy and a Soviet type of 1.8 to 2 million tpy; at one location, one or more basic units can be constructed. The Chinese have become very good at building more of the same, but with minor variations.

Among the new large refining and petrochemical complexes being built or just completed are Whampoa (Kwangchow or Kwangtung) near Canton, Chinshan near Shanghai, Takang (delay likely), Chekiang possibly near Hanchow, Chiuchiang in Kiangsi Province, and Urumchi in Sinkiang. Other older large refineries are located at Fushun, Taching, Lanchow, Shanghai (old one), Peking, Shengli, Talien (or Dairen), Chinhsi, Nanking, Anshan, Maoming, Yumen, Tientsin, and Karamai-Tushantzu. Much has been reported about the 7-million-tpy Peking and petrochemical complex. It fulfilled quotas by December 20, 1977, with a reported 46.7% increase in output value over that of 1976.[55] The German firms Lurgi and Zimmer and Standard Oil of Indiana will furnish important additions to Peking's petrochemical facilities. China also has small refinery-petrochemical works, such as a 50,000-tpy plant at Changchow, Kiangsu Province, which produces refined oil products, fertilizers, insecticides, chemicals and acids, plastics, resins, and medicines, etc.[56]

The Mineral Industry of Colombia

By Orlando Martino[1]

In 1977, Colombia's economic recovery continued to be slow and hesitant following the recession of 1975. The gross domestic product (GDP), estimated at $16.6 billion[2] at current prices, grew 4.5% in real terms, considerably below the pre-1974 rate of 7%. The rate of inflation was almost 30%, compared with the 26% rate of 1976.

The mineral industry of Colombia continued to be dominated by the production of crude petroleum, natural gas, and coal. Except for gold and platinum, production of metallic minerals was limited and represented only a small share of the GDP. Colombia remained a significant world producer of platinum in 1977, ranking fourth after the U.S.S.R., the Republic of South Africa, and Canada. The volume of production of minerals and mineral fuels was generally below the level of 1976. The mining sector, excluding mineral fuels, accounted for less than 1% of the GDP, 7% of exports, and 1% of employment.

During 1977, Colombia took further steps to exploit its mineral potential. Production by the extractive industries has been modest because they have been handicapped by the large investments required, the shortage of technical personnel, and a lack of transportation facilities. The Government was attaching increased importance to developing the mineral sector in order to take advantage of a significant source of employment, economic growth, and diversification away from coffee exports. The Government sought to rejuvenate its mining tradition and was encouraging development of mineral reserves with a new policy of using joint venture agreements between Government agencies and local and foreign private investors. Mining investment was also being encouraged by sales tax exemptions for imports by mining companies and special tax incentives established by the Tax Reform of 1974.

While Colombia has not actively sought foreign investment in most sectors of the economy, a favorable climate exists for potential investors in export-oriented industries located outside the major cities. On the basis of project plans and arrangements with foreign investors for financial and technical assistance, Colombia was expected to become a significant producer and exporter of copper, nickel, phosphate rock, steam coal, and liquefied natural gas (LNG). Development of coal and natural gas deposits was of particular interest as a means of providing alternative energy sources and improving Colombia's balance of payments situation. Among the Government-sponsored mining projects, further exploration and development of the Cerrejón coalfield is likely to be Colombia's most important project over the next 10 years. To reverse the declining trend in crude oil production and regain Colombia's self-sufficiency, the State-owned petroleum company Empresa Colombiana de Petróleos (ECOPETROL) was developing an exploration program to invest $116 million during the 1978-80 period. However, in the short term, except for coal and gas, overall mineral production was not expected to increase notably above historical levels.

The Instituto Nacional de Investigaciones Geólogo-Mineras (INGEOMINAS), a dependency of the Ministry of Mines and Energy, continued to expand mineral exploration supported by technical assistance from the United Nations Development Program (UNDP). By early 1977, INGEOMINAS had geologically mapped about 10% of the national territory, and more detailed exploration was accomplished in no more than 25% of the mineralized areas.

PRODUCTION

Despite the wide diversity of mineral occurrences in Colombia, mining and processing of metallic and nonmetallic minerals remained limited to a few commodities. In 1977, production of pig iron decreased 22%, and that of crude steel decreased 8%. Colombia's production of steel was among the lowest in Latin America, at 13 kilograms per person, compared with 100 kilograms per person in Argentina and Brazil.

While output of platinum rebounded, gold and silver production decreased. Output of manganese remained unchanged, and that of mined chromite dropped sharply. Among nonmetals, cement production decreased 9% after the peak output of 1976. Mining of emerald resumed in 1977 following a period of suspended operations. Output of rock salt declined slightly, but that of marine salt dropped 20%.

Among the mineral fuels, coal production increased slightly and that of natural gas increased to a record high. In contrast to a further decline in crude oil production of 6%, refinery output increased slightly.

eEstimate. pPreliminary. rRevised. NA Not available.

[1]In addition to the commodities listed, manufactured fertilizer materials and coal briquets are also produced, but output is not reported quantitatively and available information is inadequate to make reliable estimates of output levels.

[2]Figure represents emerald imported by the United States, consisting primarily of morralla and gangue but also including some emerald of gem quality.

[3]Exports.

TRADE

Over the past 5 years, Colombia has had steady expansion in its international trade. In 1977, total exports, valued at $2.3 billion, increased 30%, and imports, totaling $2.7 billion, increased 34%. However, the role of minerals is minor, contributing less than 7% of total exports in 1977.

The drop in production of crude petroleum, coupled with the growth in domestic demand, made it impossible for Colombia to resume exports of crude oil discontinued after 1974. However, Colombia continued to export residual fuel oil, mostly to the United States, from ECOPETROL's refinery in Cartagena. Of the total of 484,500 carats of emerald exported in 1977, 87% went to the United States. Shipments overseas of portland cement, in a sharp upward trend in the 1972-76 period, declined 36% in 1977 to 433,000 tons. Exports of ammonia have been declining owing to increased domestic demand for fertilizers. It was expected that Colombia would resume sizable exports of fertilizers in 1980 when the expansions of several fertilizer plants are completed. On the basis of projects being planned, Colombia was also expected to become a significant exporter of nickel, steam coal, and LNG in the 1980's. Exports of coal were projected to earn $18 million in 1980, $190 million in 1985, and $650 million in 1990. The value of major mineral-related exports in terms of payments received is as follows, in million dollars:

Commodity	1976	1977	Percent change
Fuel oil	83.9	104.6	+25
Emerald	13.2	24.2	+83
Cement	24.5	16.5	-33
Platinum	1.7	.9	-47
Other	5.2	10.6	+104
Total	128.5	156.8	+22

Digitized by Google

Imports of crude oil, received at the rate of 25,750 barrels per day mostly from Venezuela, were valued at $131 million. These imports, together with imports of refinery products, mostly from Brazil and Aruba, required $187 million in foreign exchange in 1977. Imports of iron and steel amounted to $133 million. Colombia continued to rely heavily on imports to satisfy its demand for nonferrous metals, especially aluminum, copper, lead, and zinc. In 1977, imports of earth-moving and mining equipment amounted to $30.5 million, 62% of which were from the United States. Although overall imports from the United States increased 21% in 1977, their share in the Colombian market dropped from 38% to 34%, largely because of the rapid growth of petroleum imports.

Table 2.—Colombia: Exports of mineral commodities

COMMODITY REVIEW

METALS

Aluminum.—Colombia continued to rely primarily on imports of ingots, mostly from Venezuela, to meet its growing demand for aluminum. In 1977, ingot imports amounted to 13,000 tons valued at $15 million. Imported bauxite was apparently utilized in nonmetallic industry applications, whereas the ingot and semimanufactures were processed by several rolling and extrusion mills.

Chromium.—Production of chromite has increased greatly since 1959 when an output of 40 tons of ore was first reported, although 1977 registered a sharp decline. Cromitas Ltda., a subsidiary of Coltejer S.A., one of the largest textile producers in Colombia, continued to be the only producer, near Medellín. Feasibility studies were being conducted to expand production. Most of the chromite was exported to the United States.

Copper.—Colombia continued to rely on imports of primary copper to meet domestic demand. Copper imports have increased steadily in line with Colombia's increased industrialization and growth in population.

INGEOMINAS, with assistance from the UNDP, completed prefeasibility studies of the porphyry copper deposits of Pegadorcito-Pantanos and Murindó, discovered in the adjoining Departments of Antioquia and Chocó. Empresa Colombiana de Minas (ECOMINAS), a State-controlled agency, was designated to develop these deposits. Financial assistance of $3.4 million was being sought from the World Bank's Consultative Group for Colombia and from the Canadian International Development Agency (CIDA).

INGEOMINAS has been involved in studies since 1970 to determine the amount and quality of other copper deposits at Rovira (Tolima), El Pismo and Silva (Cauca), Mocoa (Putumayo), and Patasery and El Encanto (Nariño). To date, 500 million tons of potential copper ore has been identified.

Gold, Platinum, Silver.—Colombia was the second leading gold producer in Latin America in 1977 and ranked 12th worldwide. In the period 1972-75, gold output increased at an average annual rate of 21.5%. Following the small decline of 3.5% in 1976, output decreased 12% further in 1977. A 20% increase is expected in 1978.

During 1977, foreign companies exploiting gold, platinum, and silver in Colombia were purchased by a newly formed Colombian private corporation, Mineros Colombianos S.A. This corporation, which owns and operates over 60 mines, operated six dredges in the Departments of Antioquia and Chocó and was planning to purchase another dredge for use in 1978. Platinum was produced as a byproduct of gold from deposits primarily in Chocó. Output of platinum, which had been declining since 1973, rebounded in 1977. Output of silver, which had been increasing at an average annual rate of 13% since 1972, decreased 14% in 1977. The Department of Antioquia was the major silver producer.

The Government established an 8% export subsidy and raised the internal price of gold in order to increase production, especially by the small and medium miners.

Iron Ore.—Output of iron ore came from Colombia's largest mine, located near Paz del Río northeast of Tunja in the Department of Boyacá, where the country's major iron and steel producer, Acerías Paz del Río S.A. (PDR), is located. In 1977, PDR produced 459,000 tons of iron ore, a decrease of 8%. The company's captive mines near Tunja are exploited chiefly by adit. Smaller output has come from mines at Pacho and Tibirita in Cundinamarca. In 1977, Colombia consumed 541,000 tons of iron ore in its steel operations, 56% of which was sinter ore.

PDR has estimated its iron ore reserves at 226 million tons, adequate to meet steel production needs for 35 years. Only 5 million tons at Paz del Río are open pit reserves. In addition, iron ore deposits have been found in eight other areas estimated to contain 124 million tons, of which 75 million tons is considered minable. Colombian iron ore is relatively low quality, with a 43% to 45% iron content and 11% silica content, making continued imports of higher quality ore necessary.

Iron and Steel.—Colombia's crude steel production supplied only 41% of domestic demand, which was estimated at about 800,000 tons per year of flat and formed products. The annual growth rate of consumption was 6.4% for the period 1953-75 but is projected at 8.2% through 1990. At the end of 1977, total installed capacity of 550,000 tons per year comprised one integrated steel mill (operated by PDR), six semi-integrated plants, and a pig iron producer (operated by Colombiana de Arrabio S.A.).

On the basis of project feasibility studies reviewed by Dastur Engineering International of India, PDR, the largest steel pro-

Digitized by Google

ducer since 1950, was planning to expand its annual steel capacity in three stages: From 300,000 tons to 400,000 tons by 1979, then to 600,000 tons, and to 1 million tons by 1985. The project plans included purchase of a large arc furnace and a cold-rolled laminated steel facility. PDR has its own reserves of iron ore, coking coal, and limestone.

Dastur submitted a sector plan, financed by the United Nations Industrial Development Organization (UNIDO), for expansion of Colombia's iron and steel sector to meet future demand. The plan includes establishment of a new integrated steel plant on the Atlantic coast near Barranquilla with a capacity of 1.3 million tons per year and two direct-reduction plants to produce 220,000 tons and 350,000 tons of sponge iron per year. The direct-reduction plants would utilize the new natural gas reserves discovered on the northern coast of Colombia and would probably rely on imported iron ore of higher quality. Dastur won the bid to prepare the feasibility studies for the two plants with local financing from the Fondo Nacional de Desarrollo (FONADE).

Although Colombia produces some ferromanganese and other ferroalloys, it depends mostly on imports to meet its needs. Consumption of ferroalloys in 1977 was 8,713 tons, a sharp increase of 66% over that of 1976.

Manganese.—Production of manganese ore and concentrate has increased greatly since 1970 when output of 50 tons was first reported. Output in 1977 again fell far short of the record high level of 14,000 tons achieved in 1975. Although mining licenses have been issued covering deposits in Antioquia, Caldas, and Valle, only Antioquia had active mines, at Edabeiba and Santa Bárbara. No official estimates of manganese reserves were available.

Nickel.—Although the Government had signed a mining concession contract in July 1970 to develop the Cerro Matoso nickel deposit, work had not been initiated by the end of 1977 owing to the lack of external financing and assured markets and depressed nickel prices.

Empresa Colombiana de Niquel (ECONIQUEL) and Cía. de Niquel Colombiano S.A. (CONICOL), comprising Hanna Mining Co. of Cleveland and Standard Oil Co. of California, were involved in a joint venture to exploit the Cerro Matoso lateritic deposit located in the Montelíbano District of the Department of Córdoba. Bechtel Corp. (United States) completed a feasibility study of the $300 million mine and smelter project that was originally estimated to cost $100 million in 1970. Although long-term sales contracts had not been signed and World Bank and supplier financing of $85 million was not assured, the Government and Hanna Mining agreed in September to proceed with the Cerro Matoso project. ECONIQUEL and CONICOL were in the process of contracting Bechtel to supply and install the plant, and construction was expected to start by the end of 1978.

The plant would have a capacity for processing 850,000 tons per year of ore to produce 19,090 tons (nickel content) of ferronickel to cover domestic consumption and export. Exports were projected at $90 million per year. At yearend, Hanna Mining was negotiating with Japanese interests to purchase 15% of the output.

The estimate of proved reserves of nickel ore was revised upward to 42 million dry tons with an average nickel content of 2.5%.

NONMETALS

Asbestos.—Minera Las Brisas S.A., a private company with 27% foreign capital, continued to develop and implement a $23 million asbestos project located 160 kilometers north of Medellín (Antioquia) and 16 kilometers from Campamento. Eternit Colombiana S.A., the principal Colombian producer of asbestos-cement products, also participated in the equity of Minera Las Brisas. Initial production of 9,000 tons of asbestos fiber per year was scheduled for 1979, with expansion to 18,000 tons per year planned for 1980. Until then, Colombia will continue to depend entirely on imports to meet its asbestos fiber needs. Domestic demand was 17,000 tons in 1975.

Studies completed by Nicolet Industries Inc. of Ambler, Pa., showed that proved reserves of the asbestos deposits in the Las Brisas area are 6.4 million tons, including 2.0 million tons of marginal reserves, capable of producing 390,000 tons of asbestos fiber. The Las Brisas deposit was first explored in the 1950's and was further drilled by Nicolet in 1964 under a concession.

Cement.—The first cement plant was established in Colombia in 1905, and with the startup of the newest plant at the end of 1977, total installed capacity increased to 5.1 million tons. A total of 15 cement companies operated 42 furnaces. Since the early 1950's, internal demand has been met entirely by domestic production, and exports have grown sharply. Table 4 shows cement production and exports since 1973 and projections for 1978. Colombia has the fifth largest cement capacity in Latin America.

Cía. Colombiana de Clinker opened a new cement plant at Cartagena on the Atlantic coast in December 1977, the first company to open a new cement plant since 1969. The initial capacity of 600,000 tons per year was expected to be expanded to 1 million tons, with most of the output for export. Cementos Samper S.A. at Bogotá and Cementos El Cairo S.A. at Medellín were planning to construct new plants with capacities of 18,000 tons and 36,000 tons per year, respectively, for operation in 1979. At yearend, the National Planning Department rejected (based on a feasibility study) a proposal to install a 640,000-ton-per-year plant at Belencito (Boyacá).

Since oil and natural gas prices have risen sharply, several cement companies were planning to convert from fuel oil to coal, especially those companies located near abundant coal sources.

Fertilizer Materials.—*Phosphate.*—Colombia imports some 90% of the phosphates used in its fertilizer industry, which is located in the port cities of Barranquilla and Cartagena, far distant from the nation's main agricultural regions. Colombia has 15 known phosphate deposits containing 625 million tons of ore with an average P_2O_5 content of 20%. The two largest deposits alone, in the localities of Pesca and Sogamoso (Boyacá), contain a total of 495 million tons. The richest deposit, with a 28% P_2O_5 content, is at Sardinata, but only 9 million tons of ore is available.

Prefeasibility and beneficiation studies were done by the Japan Consulting Institute and the International Development Center of Alabama for the installation of a 2,700-ton-per-day phosphate mining and treatment plant at Pesca (Boyacá) and an 800-ton-per-day mining project at Sardinata (Norte de Santander). In early 1978, ECOMINAS was expected to contract for a feasibility study for a $70 million phosphate mining and fertilizer program. During 1977, the Inter-American Development Bank approved a $1.7 million loan to help finance this study. ECOMINAS and the Instituto de Fomento Industrial (IFI) will be responsible for this development program during 1978-80.

Gem Stones.—*Emerald.*—Colombia has been famous for its emerald since 1567 when the first mining company was organized to exploit emerald in the Muzo and Coscuez region of Boyacá. Since July 1974, when the mines were closed by the Government because of unrest and violence, the areas have been under the control of the national police. During 1977, the Government, through ECOMINAS, signed lease contracts with several private companies to resume mining operations at Muzo, Coscuez, and Peñas Blancas. Contracts were for 5 years, extendible to 10 years.

During the last part of 1977, the private companies made new investments in equipment, roads, and other infrastructure. Considerable investment was required to improve methods of extraction and mining efficiency. Total emerald production has been difficult to estimate because of contraband shipments; official data cover legal exports.

Limestone.—PDR exploited its own limestone deposits. The steel company's estimated total reserves were about 116 million tons, of which the 11 million tons classified as measured reserves will be adequate to meet expanded steel needs for only 7 to 10 years. Most of the companies in the cement industry have Government licenses to exploit limestone resources.

MINERAL FUELS

The following tabulation gives the sources of Colombia's energy consumption as a percent of the total, with projections for 1985:

	1965	1975	1985
Coal	22	18	14
Natural gas	11	13	14
Petroleum	53	52	50
Hydroelectric energy	14	17	22

Source: Latin America Economic Report. Aug. 5, 1977.

Colombia's total installed electrical generating capacity is covered 30% by thermal plants using diesel oil, fuel oil, gas, or coal. As of December 1976, steam plants using coal represented only 9.4% of electrical generating capacity. By July 1977, Colombia had 22 hydroelectric plants in operation, with a generating capacity of 2,584 megawatts, and 9 plants under construction, to bring total capacity to 3,337 megawatts. Colombia's total hydroelectric potential, located in 351 sources, was estimated at 118,000 megawatts.

Coal.—Although Colombia has the largest known coal reserves in Latin America, the level and annual growth rate of coal production have been low. An extensive survey of coal-producing areas of Colombia conducted by the Ministry of Mines and Energy in 1975 revealed that 626 coal mines were active in 9 departments, employing 8,700 workers. The largest production was from Boyacá, followed by the Departments of Cundinamarca and Antioquia. There were only three large mines with production of over 120,000 tons per year, and they accounted for 41% of the country's total output. The largest coal mine, producing 600,000 tons per year, was La Chapa at Belencito (Boyacá), owned by PDR. The steel company's coking coal reserves were estimated at 198 million tons, of which 44 million tons was measured reserves.

Table 5 shows consumption of coal during 1977 by the various industrial sectors. The steel industry consumed 203,000 tons of coke. The Ministry of Mines and Energy projected that to meet the growing demand of these sectors, 6.1 million tons of coal would be required in 1980, 10.9 million tons in 1985, and 13.1 million tons in 1990.

Carbones de Colombia S.A. (CARBOCOL), a State-controlled company formed in 1976, continued plans to develop Area A of the Cerrejón coal basin located in the Department of La Guajira. Initial production at the rate of 350,000 tons per year, using labor-intensive methods, was expected by the end of 1978, to be used domestically to replace fuel oil in cement production. Area A is estimated to have 120 million tons of reserves exploitable by open pit methods and 300 million tons exploitable by deep shaft. The Cerrejón coal appears to be a low-sulfur (less than 0.5%) steam coal; volatile matter ranges from 38% to 42%; fixed carbon is 54% to 56%; and the calorific value is 13,500 Btu per pound.

International Petroleum (Colombia) Ltd. (INTERCOL), Exxon Corp.'s Colombian subsidiary, continued its drilling program in the larger Area B of the Cerrejón Basin, under a joint venture with CARBOCOL. INTERCOL started drilling in December 1976 and was expected to select a mining site after 3 years under the association contract. If feasibility studies are favorable, the preliminary target date for initial coal output of 1 million tons per year would be 1981. Area B is estimated to have 300 million tons of reserves minable by open pit and another 1 billion tons requiring underground mining. Alternative export transportation routes to the Atlantic coast were

under study.

The coking coal of the central region was being explored by Spain, Romania, and Brazil under bilateral agreements. Another coal deposit that CARBOCOL is interested in developing with foreign participation is the San Luis deposit near Santander, which has an estimated 180 million tons of reserves. CARBOCOL has invited foreign companies to begin initial talks regarding prefeasibility studies.

Natural Gas.—Gross production of natural gas increased to a new record high in 1977 of 122 billion cubic feet. Of the total, 50% was used by industry, 8% was used as fuel, 21% was flared, and 18% was reinjected. In August, Promisgas S.A., with ECOPETROL and Texas Petroleum Co. as major shareholders, inaugurated a 380-kilometer pipeline from the Ballena gasfield in La Guajira Department to Cartagena. Gas reserves in the three La Guajira fields of Ballena, Chuchupa, and Ríohacha were estimated at 3.5 trillion cubic feet, 90% of the country's total. In addition to supplying the energy needs of industries in the Barranquilla-Cartagena area, the Government was planning to use the La Guajira nonassociated gas for electrical generation, an LNG plant at Palomino, and an ammonia and urea complex. Following an invitation for bids by ECOPETROL and Texaco Inc. in early 1977, El Paso Co. signed a letter of intent for the development of the 150-million-cubic-foot-per-day La Guajira LNG plant. Exports of LNG, mostly to the U.S. eastern seaboard, were projected to eventually reach $130 million. In December 1977, distribution of consumer gas was initiated in Barranquilla, the fourth largest city in Colombia.

At yearend, Colombia's total natural gas reserves in eight known gasfields were estimated at 3.9 trillion cubic feet. The poten-

[4]Includes gas used by oil companies for fuel.

tial of the gas deposit discovered in summer of 1977 by the ECOPETROL/Texaco/Amoco Colombia Oil Co. group offshore Cartagena was being evaluated. With the completion of the Ballena-Cartagena pipeline, Colombia's gas pipeline system totaled 1,456 kilometers with a capacity of 644 million cubic feet per day.

Petroleum.—Colombia ranked seventh among Latin American crude oil producers, preceded immediately by Brazil and Ecuador. Production of crude petroleum, which averaged 138,000 barrels per day, decreased for the seventh consecutive year since the peak year of 1970 when 80 million barrels was produced. The Orito field in Putumayo continued as the largest single crude oil producer. However, the Middle Magdalena Basin accounted for nearly one-half of overall output. The new prices established by the Government for marginal crude oil resulted in additional production of 19,500 barrels per day and new production of 2,300 barrels per day. Production from established oilfields declined 12% to 115,000 barrels per day. The petroleum industry projected that production from old fields would continue to decline through 1980 at a rate of 10% per year but that marginal crude oil production would increase 15% per year. Increased exploration activity may change the outlook by the early 1980's so that Colombia may become self-sufficient again in 1985. As of December 1977, Colombia's proved oil reserves were estimated at 980 million barrels. A study by ECOPETROL indicated that Colombia has possible recoverable oil reserves of 7 billion barrels in 13 sedimentary basins; however, 75% of the structures still await test drilling.

For the third consecutive year, domestic demand for crude oil in 1977 exceeded Colombia's output, making it necessary to import 9.4 million barrels—this is in contrast to 1970 when 32 million barrels of crude was exported. The value of crude oil imports increased 55% to $131 million, and that of refinery product imports increased 46% to $56 million. The negative impact of these imports on Colombia's trade balance was moderated in 1977 by exports of 8.6 million barrels of residual fuel oil valued at $105 million. Imports of crude oil were projected at 21 million barrels in 1978, 44 million barrels in 1979, and 63 million barrels in 1980.

Consumption of petroleum products increased only 3.4% in 1977. The low growth resulted from a sluggish economic recovery and increased prices. The price of regular gasoline was raised 250% but remained below the marginal cost of crude oil. Regu-

Digitized by Google

lar gasoline was priced at $0.27 per gallon, compared with $0.83 in Argentina, $0.91 in Chile, and $1.51 in Brazil. Only Venezuela and Ecuador had lower prices.

The pricing policy for new and incremental crude oil production adopted by the Government in May 1976 stimulated renewed interest in exploration in Colombia. The number of exploration wells drilled increased to 30 from 17 in 1976, and 50 exploration wells were planned for 1978. During 1977, ECOPETROL, formed in 1951, signed eight new association "risk" contracts, which replaced the concession system, for a total of 70 contracts signed since 1955; at yearend, however, only 28 contracts were active.

The Government decided to postpone construction of the 70,000-barrel-per-day refinery at the Pacific port of Tumaco, the terminus for the trans-Andean pipeline from Putumayo. Colombia's gasoline shortage was expected to be alleviated but not eliminated when expansion of the Barrancabermeja refinery to 140,000 barrels per day is completed.

Uranium.—In October 1977, a new State company was formed, Empresa Colombiana de Uranio (COLURANIO), based in Bucaramanga (Santander), to explore, develop, and market the country's uranium resources. The shareholders of COLURANIO comprised ECOPETROL, the Instituto de Asuntos Nucleares de Colombia (IAN), ECOMINAS, INGEOMINAS, Corp. Eléctrica de la Costa Atlántica (CORELCA), and the Instituto de Interconexión Eléctrica, the company in charge of constructing a national electric grid system.

During 1977, IAN (created in 1955) signed contracts with Empresa Nacional del Uranio S.A. (ENUSA) of Spain and Minatome S.A. of France covering exploration for uranium in several departments. In the contracts, IAN has 51% participation, with the foreign company holding 49%. COLURANIO was expected to take over management of the exploration contracts arranged by IAN.

Cía. Minera de Uranio, the only private enterprise exploring for uranium under an association contract, found a uranium deposit at California (Santander) with reserves of 150,000 tons of ore. By 1980, Colombia expects to be producing 1,000 tons per year of uranium concentrate. Since natural gas, coal, and hydroelectric power are cheaper sources of energy in Colombia, electrical generation by nuclear plants was not expected until the year 2000. Nevertheless, the development of any uranium potential would provide Colombia with another energy option for the longer term.

The Mineral Industry of Cyprus

By T. John Rowland, Jr.[1]

The Island of Cyprus remained divided into two sections in 1977, as it has been since hostilities ceased in 1974. The Federated Turkish Cypriots (FCS) occupied the northern sector, and the Government of Cyprus controlled the southern sector. Information concerning the mineral industry of the FCS sector was not available; as a result, this chapter is based on the Cypriot Government's reports.

The mineral industry in 1977 consisted of the production of chromite, copper, asbestos, bentonite, cement, mineral pigments, and pyrite. The considerable decline in mineral exports caused by the 1974 hostilities led to a diversification of the Cypriot mineral industry. Increased emphasis was applied to exploration and exploitation of nonmetallic minerals. Concurrently, the Geological Survey Department (GSD) extended aid to the Government and private industry for the revitalization of the construction materials industry, including investigation of limestone, clay, barite, and diabase deposits. Revitalization of the construction industry resulted in a shortage of aggregates, especially sand. The Mineral Deposits Section of the Department of Mines investigated various occurrences of diabase for the location of rock suitable for production of crushed aggregate. Exploration revealed four areas: Monagvovilli, Pareklisha, Phikardhou, and Gourri.

Exploration work for locating massive new cupriferous sulfide deposits consisted of an intensive program begun by Noranda Exploration (Cyprus) Ltd. in collaboration with the GSD and Hellenic Mining Co. Ltd. (HMC). A geophysical and geochemical survey was conducted over areas covered by the mining leases and property permit of HMC, requiring an expenditure of $396,000.[2]

The GSD stated that 122 new quarry licenses were granted covering sand and gravel, marble, gypsum, limestone, pigments, and clay. During the year, 8 new prospecting permits were issued, 96 were extended, and 22 were canceled. There was only one oil exploration licence in force, for an onshore area of 310 hectares.

HMC planned to construct a fertilizer complex at Vasilikos on the southern coast of Cyprus. The facility, scheduled to be completed in 1979, is to include production units for sulfuric acid, phosphoric acid, and nitrogen-phosphorus-potassium (NPK) fertilizers. The sulfuric acid plant, to be built by the U.S.S.R., will have a capacity of 180,000 tons per year and will utilize imported phosphate rock. The Lurgi Group of the Federal Republic of Germany was contracted to design the 4,000-ton-per-year phosphoric acid plant and the 150,000-ton-per-year NPK fertilizer plant.

PRODUCTION AND TRADE

Mineral production in Cyprus in 1977 was generally similar to that of 1976. Production increases were recorded for asbestos (6%), chromite (55%), sand and gravel (57%), and umber (35%), while decreases of 15% were recorded for both iron pyrite and copper concentrates. Cyprus Petroleum Refinery Ltd. (CPR) operated near capacity throughout the year.

Mineral commodity exports represented

Digitized by Google

about 7.6% of the total value of exports of the Island. In 1977, mineral exports totaled 257,360 tons, increasing 5.3% over the 1976 tonnage, but the monetary value of the exports decreased 3.3% as a result of world economic conditions. The tonnage of iron pyrite exports increased 13.9%. Copper pyrites were not exported in 1977. Exported copper concentrates decreased 33% in tonnage and 47% in value. Asbestos fiber exports increased 7.6% in tonnage and 33% in value. Chromite exports increased 28% in value but only 6% in tonnage.

COMMODITY REVIEW

METALS

Chromite.—HMC operated two chromite mines and remained the sole chromite producer in Cyprus. The Kokkinorotsos mine recorded an output of 27,500 tons of ore, from which 13,619 tons of chrome concentrates was produced. The other chromite mine, Kannouves, extracted 1,000 tons of ore, which yielded 612 tons of concentrates. Essentially all of the chrome concentrates were exported to Europe.

Copper.—Three companies were engaged in copper production during 1977. Cyprus Sulphur & Copper Co. Ltd. continued operation at the Limnia open pit mine and produced about 12,800 tons of copper concentrates of 23.3% copper. HMC operated four copper mines with a total production of 14,800 tons, a 92% increase over 1976 output. Kampia Mines Co. terminated operations at its Peristeria copper-zinc mine but planned to resume operations after installation of a concentrator for low-grade ore.

Noranda, in association with the GSD and HMC, embarked on an intensive exploration program for new cupriferous sulfide deposits near Klirou. Three prospects covering 2,000 hectares were investigated in detail. The results indicated copper-bearing sulfide mineralization. At yearend, the economic potential of these deposits was under intensive investigation.

NONMETALS

Asbestos.—Production of chrysotile by Cyprus Asbestos Mines Ltd. (CAM) increased 12% over that of 1976. CAM milled over 2,333,000 tons of ore to produce about 18,000 tons of long-fiber and 14,160 tons of short-fiber asbestos. The United Kingdom, Denmark, Greece, and Ireland were the principal importers of Cypriot asbestos.

Barite and Celestite.—A small deposit of barite and celestite was located near the village of Maroni. Detailed mapping, geophysical prospecting, and drilling operations were conducted on the deposit and surrounding area. Results of the investigation were not published by yearend.

Cement.—Cyprus Cement Co. Ltd. and Vassiliko Cement Works Ltd. were the principal cement producers in 1977. Cyprus Cement operated a quarry and plant. A total of 583,000 tons of white and yellow marl was quarried, along with lesser amounts of soft marl and havara. Clinker production totaled 330,000 tons, and cement output totaled 347,000 tons. Vassiliko quarried over 865,000 tons of limestone and 444,000 tons of clay. Production included 660,000 tons of clinker and 676,000 tons of cement. About 38% of the cement was sold locally.

Clays.—*Bentonite.*—Extensive exploration and laboratory work was conducted by the GSD on various occurrences of bentonite in Cyprus. Exploration included sinking 108 drillholes which verifed extensive bentonite reserves in the area of Phinikaria, Kannaviou, and Sotira. Laboratory investigations were continuing after promising preliminary results.

Mineral Pigments.—The 1977 production of umber increased 35% and production of ocher decreased 31% from 1976 levels. Estimated exports of umber were 9,900 tons, and exports of yellow ocher were 250 tons. The United States and the United Kingdom were the main recipients of umber.

Pyrite.—Production of iron pyrite decreased 15% in 1977. HMC produced iron pyrite with an average sulfur content of 46.5% at the Mathiati mining operation. New discoveries of iron pyrite were not reported during the year.

MINERAL FUELS

CPR operated a refinery on the southern coast at Larnaca, owned by Mobil Oil Corp. (34%), Shell Oil Co. (25.5%), British Petroleum Co. Ltd. (25.5%), and the Cypriot Government (15%).

Crude oil imports amounted to 2,568,180 barrels, supplied by Iraq (68%), Algeria (24%), Saudi Arabia (5%), and Libya (3%). Refinery output was consumed domestically and included jet fuels, 260,000 tons of fuel oils, and other products.

The Mineral Industry of Czechoslovakia

By Tatiana Karpinsky[1]

Czechoslovakia is one of the most industrialized countries in Europe, but its mineral resources are limited. The economy continued to experience slow overall growth in 1977. The 1977 national income increased 4.5% over that of 1976[2] to an estimated 438 billion Czechoslovak Korunas (Kcs).[3] The State plan had envisaged an increase of 5.2%.[4] The slower rate of national income growth was due to shortcomings in building construction, and transportation.

In 1977, the gross industrial production increased 5.7%, 0.4% over the target set in the annual State plan; it contributed about 67% of the national income, of which the mineral industry (mining and quarrying) contributed 5.8%. The share of coal production was 4.3%; crude petroleum, 0.1%; metal ores, 0.7%; and other mining, 0.7%.

Compared with 1976 figures, the following increases in mineral production were reported in 1977: Brown coal 4.4%, crude steel 2.5%, rolled steel products 1.9%, petroleum products 7.4%, nitrogenous and phosphatic fertilizers (nutrient content) 6.6% and 3.5%, respectively, and cement 2.1%. Bituminous coal production decreased slightly. Production of electric energy increased 5.8%. Small amounts of copper, lead, tin, tungsten, and zinc were mined locally, with some increase in production. The bulk of nonferrous metals was imported, mainly from the U.S.S.R.

A major problem for Czechoslovakia is its reliance on imports of energy and raw materials, both of which are in short supply. However, there are large reserves of antimony, brown coal, kaolin and other clays, graphite, limestone, magnesite, mercury, uranium, and building materials in the country.

In 1977, Czechoslovakia continued to participate in the expansion of iron ore and nonferrous metals extraction and processing in the U.S.S.R. and continued to supply the U.S.S.R. with equipment for strip mining, transporting, and dressing of ores.[5] In return, Czechoslovakia is to obtain additional deliveries of Soviet aluminum, copper, iron ore, concentrates, and lead.

In 1977, the following major new facilities were put into operation in Czechoslovakia: The Chabrovice coal open pit, blocks 1 and 2 of the Pocerady 11 powerplant, block 1 of the Chvaletice powerplant, and new facilities at the Kladno steel plant.

In view of the difficult situation in the supply of domestic fuels, Czechoslovakia was intensively developing its nuclear power industry. In this regard, Czechoslovakia relies on the cooperation of the U.S.S.R. and other Council for Mutual Economic Assistance (CMEA) countries.[6] In 1977, the Klement Gottwald Steel and Engineering Plant in Ostravá continued the development of its nuclear program at the cost of about 600 million Kcs.[7]

It is planned to invest "billions of Korunas" in the mineral industry in order to increase production of nonferrous metals by 1990. This is to include production of antimony, cadmium, copper fluorite, gold, lead, rare-earth elements, silver, tin, wolfram, and zinc. Long-range plans for the development of the mining, processing, and refining of domestic nonferrous metal ores were adopted by the Government.

Government Policies and Programs.—The goals of the 1978 State plan have been set to insure attainment of the objectives of the economic policy adopted by the 15th Congress of the Communist Party of Czechoslovakia.[8] According to the plan, the gross national product is to increase 4.6% in

Digitized by Google

1978. Of this total, industry is to contribute 67.0%, construction 10.5%, agriculture 10.5%, and other production sectors 12%. The national income is to increase 5% in 1978. More than 90% of this increase is to be achieved by an increase in labor productivity.

Industrial production is to increase 5%. The plan sets the following growth rates for individual mineral sectors in 1978: Ferrous and nonferrrous industry 3.7%, power 3.9%, engineering 6.4%, and building materials 5.7%.

The manufacture of equipment for nuclear powerplants is to increase 58% and the manufacture of machinery and equipment for strip mining, overburden, and transportation of coal by belt conveyors, is to increase 38%. The following increases are anticipated in the production of selected mineral commodities in 1978:[9]

Crude steel	1.8
Rolled steel products	2.4
Steel pipe	1.1
Cement	4.6
Coal	2.5
Coke	0.2

In capital construction, attention is focused mainly on projects with budget costs that exceed Kcs2 million. According to the plan, major production capacities to be put into operation in 1978 include brown coal, 5.4 million tons; electric power, about 1,000 megawatts; cement, 269,000 tons; and sulfuric acid, 200,000 tons.

To prevent a further increase in the scope of unfinished projects, new capital construction was reduced in all sectors except fuels, power, and chemicals. In addition, increased efficiency was made one of the conditions for the implementation of general plans of development.

PRODUCTION

Coal is important to Czechoslovakia since it is the major industrial fuel. In 1977, output of bituminous coal, lignite, and brown coal was 121.8 million tons, an increase of 2.9% over that of 1976. About 86% of the bituminous coal production came from the Ostravá-Karviná basin. At year-end, development of the new Darkov mine, with projected capacity of more than 2 million tons per year, had started in the basin. About 73% of the brown coal output in 1977 came from the North Bohemian Basin. This basin is the main supplier of fuel to the growing number of large Czechoslovak powerplants.

Production of iron ore in 1977 remained far below the expanding national requirements. In addition, 16 million tons of iron ore was imported during the year, 3.9% more than in 1976. In 1977, output of pig iron, crude steel, and rolled steel products grew at about the same rate as in 1976. One of the main development targets of Czechoslovakia's ferrous metals industry in 1977 was the reconstruction of the Kladno steel plant.

The rapid development in the refining industry was made possible by supplies of crude oil from the U.S.S.R. In 1977, about 17.5 million tons of crude oil was processed, 3.5% more than in 1976.

Production of natural gas increased from 982 million cubic meters in 1976 to 1,001 million cubic meters in 1977. In addition, 7.2 billion cubic meters of gas was imported, mainly from the U.S.S.R. Czechoslovakia reported that it will have the world's largest gas transit system, capable of carrying 53 billion cubic meters of gas, by the mid-1980's. (In 1977, the flow of gas from U.S.S.R. to East and West Germany, Austria, Italy, and Czechoslovakia was estimated at 22 billion cubic meters).

In 1977, the Czechoslovak Government reported that the ore reserves in the country were much larger than had been estimated. It was expected that production of antimony, copper, lead, and zinc will increase considerably after 1980.

Total	do.	107,376	109,874	112,711

[e]Estimate. [p]Preliminary. [r]Revised. NA Not available.

[1]In addition to the commodities listed, arsenic, feldspar, gold, graphite, uranium, and a variety of additional petroleum products are produced, but information is inadequate to make reliable estimates of output levels.

[2]This material, although reported as manganese ore, is believed to be manganiferrous iron ore with a manganese content of about 17%, and, as such, is not equivalent to materials reported elsewhere as manganese ore, which generally contain 25% Mn or more.

[3]Includes gas produced from coal mines; gross output of natural gas is not reported, but it is believed to exceed reported marketed output by a relatively inconsequential amount.

[4]Data presented are for those products reported in official Czechoslovakian sources and in the United Nations' publications; no estimates have been included for other products or for refinery fuel and losses.

TRADE

In 1977, Czechoslovakia's foreign trade turnover (exports plus imports) amounted to Kcs124,163 million, an increase of 12.7% over that of 1976.[10] Total exports were valued at Kcs60,950 million, an increase of 12.4% over those of 1976. Exports to centrally planned economy countries increased 11.8%; to developed market economy countries, 9.3%; and to developing countries, 31.9%. Tasks in exports to centrally planned economy countries were exceeded, but exports to market economy countries remained below the planned level.

The total value of Czechoslovakia's imports reached Kcs63,213 million in 1977, an increase of 12.9% over the 1976 level. Imports from centrally planned economy countries increased 13%; from the developed market economy countries, 6.6%; and from developing countries, 41.3%.

The balance-of-trade deficit decreased from Kcs3,859 million in 1976 to Kcs2,263 million in 1977. Czechoslovakia's trade balances for 1977 were as follows in million Korunas:

Council for Mutual Economic Assistance countries	-1,711
Other centrally planned economy countries	674
Developed market economy countries	-3,106
Developing countries	1,880
Total balance	-2,263

The trade deficit was mainly owing to a higher deficit in trade with developed market economy countries. In 1977, there were problems in trade with these countries arising from internal economic conditions, particularly in the areas of capacity, assortment, and quality, and the continuing unfavorable movement of prices on foreign markets.[11]

In 1977, exports of machinery and equipment contributed 51% of the total export value; fuels, mineral raw materials, and metals, 16.7%; chemicals products, 5%; construction materials, 2.2%; and other products, about 25%. Machinery and equipment accounted for 39% of the total import value; fuels, mineral raw materials, and metals 28.7%; chemical products 7.6%; construction materials, 0.8%; and other products, 23.9%.

Imports of fuels, mineral raw materials,

Digitized by Google

and metals increased 12% in 1977 over those of 1976. In 1977, Czechoslovakia's main imports included 16 million tons of iron ore, 0.8 million tons of pig iron, 1.3 million tons of manganese ores, 0.5 million tons of bauxite, 7,254 million cubic meters of natural gas, 18.3 million tons of crude oil, and 5.6 million tons of bituminous coal.

Czechoslovakia's largest trading partner was the U.S.S.R. Its share of total Czechoslovak imports was 34% in 1977, and its share of total exports was 32%. The U.S.S.R. accounted for 93% of Czechoslovak imports of crude oil, 83% of iron ore, almost 100% of natural gas, and a large quantity of nonferrous metals.[12]

In 1978, the planned increases in exports is 4.8% to centrally planned economy countries and 13% to market economy countries. The trade turnover between Czechoslovakia and the U.S.S.R. is to reach 5,500 million soviet rubles, an increase of 10% over that of 1977. The greatest increase is to be in the trading of machinery and equipment. Imports of Soviet raw materials such as crude oil, natural gas, iron ore, metals, phosphate fertilizers, asbestos, and mining and metallurgical equipment will also be increased.[13]

The German Democratic Republic was Czechoslovakia's second largest trading partner, with a share of about 11% of the total Czechoslovak imports and exports in 1977. Imports from the German Democratic Republic included deliveries of potassium salts, brown coal briquets, and chemical products. Czechoslovakia supplied the German Democratic Republic's industry with bituminous coal, foundry coke, and rolled steel products. The exchange of machinery and equipment amounted to approximately two-thirds of mutual deliveries.[14]

The wide-ranging economic cooperation between Poland and Czechoslovakia led to considerable increase in their mutual trade turnover in 1977. Czechoslovakia's exports to Poland increased 9.4%, and imports from Poland increased 6.6%. Poland supplied Czechoslovakia with bituminous coal, copper, zinc, sulfur, sulfuric acid, and nonferrous rolled metals. Czechoslovakia's deliveries included kaolin, magnesite for the brick and steel industries, cement, petroleum products, and chemical raw materials. Many branches of Poland's industry utilize the imported Czechoslovak machinery and equipment.

In 1977, Czechoslovakia exported machinery and other capital goods to Cuba and imported nickel and some copper from Cuba. Czechoslovakia, together with other CMEA countries, cooperated on the construction of a nickel and cobalt extraction and processing plant at Camarioca in the Matanzas Province, Cuba. This plant is to go into partial operation in 1981, and 2 years later is to produce 30,000 tons per year of nickel.[15]

An agreement between Czechoslovakia and the People's Republic of China on the exchange of goods and on payments for 1978 was signed in 1977. Under this agreement, Czechoslovakia will supply China with a variety of machinery and equipment and will import from China nonferrous metals and consumer goods.[16]

In 1977, Czechoslovakia participated in geological prospecting in Mongolia, Cuba, and other developing countries. Nearly 100 Czechoslovak experts were working in cuba, most in mining and geology.

The trade agreement between Czechoslovakia and Iran, signed on May 13, 1977, provided for mutual trade in 1977-78. Under this agreement, Czechoslovakia will export machinery and equipment to Iran, and import crude oil and nonferrous ores, and concentrates from Iran.

Table 2.—Czechoslovakia: Exports of mineral commodities[1]

(Metric tons unless otherwise specified)

Commodity	1975	1976	Principal destinations, 1976
METALS			
Aluminum metal, including alloys:			
Scrap	2,467	3,087	West Germany 979; United Kingdom 856; Austria 852.
Unwrought and semimanufactures	11,629	8,447	West Germany 2,552; Japan 2,187; Italy 1,139.
Copper:			
Ore and concentrate	--	733	All to United Kingdom.
Metal including alloys:			
Scrap	454	752	West Germany 672.
Unwrought and semimanufactures	4,919	6,578	West Germany 4,608; Poland 1,945.
Iron and steel:			
Ore and concentrate	56,995	22,976	All to Austria.

COMMODITY REVIEW

METALS

Antimony.—In 1977, the estimated mine production of antimony (metal content) was about 750 tons. Antimony ores were mined at Liptovská Dúbrava and at Pezinok, near Bratislava. Prospecting for antimony ores was planned to start in the near future in the Low Tatras, the Low Carpathians, and the Spis-Gemer Mountains. Preliminary findings show that there will be adequate antimony ores, with even additional export.[17]

Copper.—In 1977, mine production of copper was about 11,000 tons. Production of electrolytic copper amounted to 23,067 tons. Czechoslovakia imported 37,000 tons of copper from the U.S.S.R., 16,000 tons from Poland, 3,000 tons from the United Kingdom, and some from Zambia.[18]

During the 14 years of operation (1962-1976), the Banská Bystrica refinery has produced about 1,500 tons of copper and 4.8 tons of silver, valued at Kcs87 million. In 1977, the Banská Stiavnica and Kodrusa plants produced 220 tons of copper and approximately 0.4 tons of silver in concentrates estimated at Kcs12 million .[19] In 1977, continuous production of copper started on a trial basis at the Krompachy smelter plant.

Czechoslovakia's largest copper deposits are found in the eastern part of the Slovak Ore Mountains and at Zlaté Hory in Moravia. Smaller deposits occur in the Czech Ore Mountains and in Central Bohemia. Slovakia appears to have good prospects with regard to copper mining. It is hoped that new deposits will be found in the existing mining centers of Slovinky, Gelnica, and Hodrusa.

Investigations of ore deposits have proved that Czechoslovakia can raise its production of copper about 100% in the future. Further prospecting for copper is to continue in both the Czech and Slovak Socialist Republics.

Iron and Steel.—In 1977, iron ore production in Czechoslovakia was estimated at 2 million tons. The main ore deposits are located in the Slovak Ore Mountains and in central Czechoslovakia. In 1977, more than 15 million tons of iron ore was imported of which the U.S.S.R. provided 13.3 million tons; Brazil, 896,000 tons; Sweden, 521,000 tons; India, 446,000 tons; and Algeria, 88,000 tons.[20]

Production of pig iron in 1977 increased 201,000 tons, 2.2% over that of 1976 to 9.7 million tons. Pig iron production is planned to exceed 10.5 million tons in 1980. Imports of pig iron in 1977 reached 833,000 tons. In 1977, Czechoslovakia produced 15.0 million tons of crude steel, an increase of 2.5% over that of 1976; the share of oxygen converter steel was 25.3%. Crude steel production is planned to reach 16 million tons in 1980.

Production of rolled steel products in 1977 increased by 196,000 tons over the 1976 level to 10.6 million tons. Foreign trade in crude and semimanufactured steel for 1975-77 was as follows, in thousand tons:

	1975	1976	1977
Exports	3,251	3,400	3,449
Imports	571	909	516

In 1977, employment in the iron and steel industry totaled 181,800 workers and employees. Total investment in the steel industry was Kcs3.7 billion. The largest metallurgical complex, the Klement Gottwald Metallurgical Works in Ostravá-Kuncice, produced more than 3.3 million tons of coke and 2.8 million tons of pig iron in 1977.

In 1977, additional facilities included renovation of a rolling mill and a unit for production of steel sheet for the manufacture of pipes at the Kladno steel plant.

In the remaining years of the sixth 5-year plan period (1976-80), the industry is to complete most of the projects for the nuclear power and pipe production. In addition, the following new projects are to be carried out in 1978: Construction of an oxygen converter plant at Trinec, with a capacity of 2.8 million tons per year of steel; continuous-casting installations at the East Slovak Iron Works; construction of a new medium-grade rolling mill and renovation of some coke batteries at the new Klement Gottwald Metallurgical Works in Ostravá-Kuncice; and a few other projects.[21]

In 1977, Loewy Robertson of the United Kingdom and Czechoslovakia signed the contract for the supply of a seamless-pipe plant to Czechoslovakia. The pipe plant to be constructed at the Chomutov metallurgical complex in 1979, will be the third of its type in the world.

In accordance with an intergovernmental agreement between Czechoslovakia and the U.S.S.R. on cooperation in the field of pro-

Digitized by Google

duction and erection of nuclear powerplants, the Vítkovice Steel and Engineering plant at Ostravá-Kuncice, the steel works at Chomutov, the General Engineering Works at Brno, and many other facilities will participate in the manufacture of nuclear equipment for reactors and nuclear powerplants. Skoda Concern, Plzen, was entrusted with the production of the complete reactors.[22] The manufacture of equipment for nuclear power engineering started in 1976.

Lead and Zinc.—Lead-zinc ores are mined at the Príbram, Kutná Hora, and Banská Stiavnica deposits. In 1977, production of lead concentrate totaled 6,973 tons and mine production of contained lead was 4,242 tons. Smelter production was reported at 19,015 tons. Soviet lead deliveries totaled 28,000 tons and Yugoslav deliveries, 2,000 tons in 1977. Production of zinc ore amounted to 777,000 tons and zinc concentrate, 18,736 tons. Zinc mine production was estimated at 9,368 tons. In 1977, imports of zinc from the U.S.S.R. amounted to 21,000 tons; from Yugoslavia, 14,000 tons; from Bulgaria, 3,000 tons; from Finland, 3,000 tons; and from Poland, 1,000 tons.

During 1977, prospecting for polymetallic ores centered in former mining districts (Spania Dolina, Zlatno, and Banská Stiavnica). Some new ore deposits were found in the used pits at the greater depths. Production of lead and zinc in Czechoslovakia is expected to increase 200% and 260%, respectively, by 1980.[23]

Tin.—A new deposit of tin ore (SnO_2) has been discovered in commercial quantity near Medvedí Brook, in the vicinity of Hnilec Village in the Carpathians. The ore vein has a diameter of about 2 to 3 meters. Reserves have been estimated at 2 million tons of tin ore.[24]

In 1977, 3,196 tons of tin was imported, of which 982 tons was from Bolivia, 690 tons from Indonesia, 596 tons from the United Kingdom, 350 tons from Malaysia, and 100 tons from France.

Uranium.—Czechoslovakia is the leading producer of uranium in Eastern Europe. Uranium production is centered at Hamr-na-Jezere in Northern Bohemia, in the Príbram area in Central Bohemia, and in Western Bohemia.

The Czechoslovak uranium industry grew considerably after 1945, when new mines opened in several parts of the country. Uranium production is centrally controlled and headed by the enterprise Czechoslovak Uranium Industry (CSUP), established on the basis of the agreement signed by the Czechoslovakia and Soviet Governments on November 23, 1945. According to this agreement, the U.S.S.R. is supplying machinery and equipment for development of the uranium industry and Czechoslovakia is delivering radioactive raw materials to the U.S.S.R. Soviet-made equipment was used to sink new shafts in the Jachymov area, and later in the Príbram area and other places.

In 1977, the Western Bohemian uranium mines were testing the Soviet-made stope hoists, and the Hamr-na-Jezere uranium mines were testing the Soviet 4-PU cutter-loader combine. Development of chemical plants in the uranium industry was also in progress. This was possible only with Soviet assistance.[25]

Data on uranium ore production are practically nonexistent because such data are classified. The deposits of uranium ore at Hamr-na-Jezere are considered relatively large and are expected to last through several decades of exploitation.[26]

Reportedly, the Príbram unit of the CSUP achieved all planned production and export tasks for the first 6 months of 1977 and attained favorable economic results. Planned exports to the U.S.S.R. were exceeded. Work at the Príbram uranium mine was concentrated at a depth of 1,400 meters.[27]

NONMETALS

Fertilizer Materials.—Czechoslovakia's chemical industry produced 604,585 tons of nitrogen and 388,928 tons of phosphatic fertilizers (nutrient content) in 1977. Production of nitrogenous fertilizers increased 6.0% over that of 1976 and phosphatic fertilizers 3.5%. It is planned to use 268 kilograms per hectare of fertilizer (nutrient content) in 1980 and about 350 kilograms per hectare by 1990.

In 1977, the U.S.S.R. delivered to Czechoslovakia 175,000 tons of phosphates (P_2O_5 content); Morocco provided 45,000 tons; Algeria, 42,000 tons; and Tunisia, Jordan, and Senegal, 45,000 tons. Imports of nitrogenous fertilizers totaling 45,000 tons came from the U.S.S.R. In 1977, Czechoslovakia also imported 627,000 tons of potassic fertilizers, of which about 75% was received from the German Democratic Republic and 25% from the U.S.S.R. There are no plans for any further increases in imports of potassic fertilizers. Problems are occurring in the case of nitrogenous and phosphatic fertilizers, with demand continuing to exceed supply.[28]

Digitized by Google

The chemical complex at Sala is the most important nitrogenous fertilizer producer in Czechoslovakia, with a 450,000-ton-per-year ammonia production. Zaluzi is the second most important plant. Other important nitrogen complexes are located at Ostravá, Strázske, and Lovosice. It is planned to start construction of a 449,000-ton-per-year ammonia unit and a 300,000-ton-per-year urea unit, both at Ostravá, northern Moravia.[29]

The country produces an urea-ammonium nitrate solution known as DAM 390. The product is now manufactured at Sala at a rate of 20,000 tons per year. In the future, Czechoslovakia hopes to increase investment in the liquid fertilizer industry.

Phosphatic fertilizers were produced at the chemical complexes at Lovosice (Northern Bohemia), at Prerov (Northern Moravia), Kolin, and at Usti (Central Bohemia), and in Bratislava (Western Slovakia).

It is planned to build six ammonium polyphosphate plants, each with a capacity of 100,000 tons per year, in the near future. At the Foska works in Prostorna, the trial operation of a new thermal phosphoric acid plant was begun. It is expected to reach full capacity in 1979; a liquid nitrogen-phosphorous fertilizer plant is planned to start in 1979.[30]

Fluorspar.—Large deposits of fluorspar are known in the Ore Mountains in northern Bohemia. The recent discovery of new deposits of fluorspar in this area has increased the reserves of fluorite ore considerably. Fluorspar deposits of less significance are located in southern Bohemia. Estimated production of fluorite ore was 90,000 tons in 1977. Czechoslovakia has only one mining enterprise for the production of fluorite concentrate, Sobedruhy, located in the Ore Mountains. Since 1975, the mine and processing plant have been renovated and enlarged.[31] It is expected that by 1985 Czechoslovakia will be self-sufficient in fluorite.

Magnesite.—Magnesite mining and processing is important at Lavinobana and other centers in Central Slovakia. Important deposits of magnesite are also located in the southwestern part of East Slovakia.[32]

Mining and processing of magnesite is increasing constantly. The plans are to increase the capacities of the larger magnesite mines while decreasing the number of small mines, as follows:

Annual capacity (thousand metric tons)	Actual 1977		Planned 1980	
	Number of mines	Ore production (thousand metric tons)	Number of mines	Ore production (thousand metric tons)
0-10	8	73	5	43
10-50	13	450	9	352
50-100	4	275	4	280
100-300	9	2,140	12	2,280
300-500	3	1,500	11	5,400
Over 500	2	2,500	4	4,600
Total	39	6,938	45	12,955

Source: Rudy (Prague). No. 6, 1977, p. 57.

Czechoslovakia is expanding the capacity of the Kosice, Podrecany, Lubeník, Burde-Poproci, and Miková mines. The Slovak magnesite mine at Lubeník produced 495,000 tons of useful ore by November 29, 1977, fulfilling the 1977 plan.

In 1977, 367,000 tons of magnesite was exported, of which 74,000 tons went to Hungary, 21,000 tons to Poland, 58,000 tons to the German Democratic Republic, 57,000 tons to the Federal Republic of Germany, and 38,000 tons to Romania.

MINERAL FUELS

Czechoslovakia's principal primary energy resources are bituminous coal and lignite. Total primary energy production derived from fossil fuel and hydroelectric and nuclear power generation was 86 million tons standard coal equivalent (SCE) in 1977, with coal and coke supplying 98%. Total primary energy consumption was 120.2 million tons SCE, with coal and coke providing about 69.5%, petroleum 20.4%, natural gas

Digitized by Google

9.1%, hydroelectric power 0.4%, nuclear power 0.1%, and imported electric power 0.5%. Primary energy balances of Czechoslovakia for 1976 and 1977 are shown in the following table 4.

Table 4.—Czechoslovakia: Supply and apparent consumption of fuels and power

(Million tons of standard coal equivalent[1])

	Total primary energy	Coal (bituminous, brown, lignite) and coke	Crude oil and refinery products	Natural gas	Hydroelectric power	Nuclear power
1976:						
Production	r84.4	82.4	0.2	r1.3	0.4	0.1
Exports	r8.0	6.5	1.5	--	--	--
Imports	r37.6	5.7	r25.1	r6.2	--	--
Apparent consumption	r114.0	81.6	r23.8	r7.5	.4	.1
1977:						
Production	86.0	83.9	.2	1.3	.5	.1
Exports	7.8	6.2	1.6	--	--	--
Imports	42.0	5.8	25.9	9.7	--	--
Apparent consumption	120.2	83.5	24.5	11.0	.5	.1

rRevised.

[1]1 ton standard coal equivalent (SCE)=7,000,000 kilocalories. Conversion factors used are as follows: Bituminous coal, 1.0; brown coal and lignite, 0.6; crude oil, 1.47; natural gas (per 1,000 cubic meters), 1.33; and hydroelectric and nuclear power (per thousand kilowatt-hours), 0.125.

[2]Includes 0.6 million tons SCE of imported electric power in 1976 and 1977.

The tendency to reduce the use of coal and increase the use of electric power generated by nuclear plants is expected to accelerate after 1980. By 1990, nuclear powerplants are expected to provide roughly one-third of the electric power produced in Czechoslovakia.

Coal.—In 1977, production of bituminous coal, brown coal, and lignite reached 121.8 million tons, an increase of 2.9% over that of 1976. The State plan for total extraction was fulfilled. Of the total coal output, bituminous coal accounted for 27.8 million tons and brown coal and lignite for 94.0 million tons. Bituminous coal production declined less than 1%, and brown coal and lignite production increased 4.1%. Bituminous coal production is expected to remain at about 28 million tons during the 1978-80 period. Brown coal and lignite output is expected to reach about 97 million tons in 1980 and 107 million tons in 1990.[28]

In 1977, about 3.3 million tons of bituminous coal was exported, of which Romania received 650,000 tons; the German Democratic Republic, 579,000 tons; Austria, 569,000 tons; Hungary, 543,000 tons; Yugoslavia, 526,000 tons; the Federal Republic of Germany, 162,000 tons; and Belgium-Luxembourg, about 150,000 tons.

In 1977, bituminous coal imports amounted to about 5.6 million tons, of which 3 million tons came from the U.S.S.R. and 2.6 million tons, from Poland.

Coke production in Czechoslovakia has stabilized in recent years at about 11 million tons. Coke exports during 1977 totaled 2.03 million tons. The German Democratic Republic, Romania, Austria, and Hungary were the largest importers. Brown coal exports amounted to 1.65 million tons, and imports were 0.32 million tons in 1977. Most of the brown coal exports went to the Federal Republic of Germany.

In 1977, approximately 55.5 million tons of coal was used for production of electric energy. In December, the Ministry of Fuel and Power estimated that coal reserves would last only into the third or fourth decade of the next century.

Bituminous coal mining in Czechoslovakia is centered in the Ostravá-Karviná Basin (Northern Moravia) and brown coal mining in the Northern Bohemian and the Sokolov Basin.

The output of the Ostravá-Karviná coalfields, most of which is suitable for coking, was 23.7 million tons in 1977. It is expected to reach 24.5 million tons in 1978 and to maintain this level until about 1990. In 1977, about 16 mines were operating and 2 more mines were under development in this basin. Coal-mining conditions over the past decade have become progressively more difficult. Coal production in Czechoslovakia is highly mechanized. In 1977, machine mining of bituminous coal in the Ostravá-Karviná coalfields accounted for 91% of

Digitized by Google

total production. Continuous miners produced about 92% of mechanized production and plows, 7%.

In the south of the Ostravá-Karviná Basin, preparations were made for the development of a new mine which is to produce high-quality coking coal at a depth of 800 to 1,200 meters. After 1990, this new output is to replace that of a number of depleted old mines.

Bituminous coal deposits are also located at Kladno (west of Prague), at Plzen, and Rosice. The output of the Kladno mining district accounted for about 8% of the total bituminous coal production in 1977. Mining activity in this distirct will probably be phased out in the 1980's and shifted to the nearby Slany deposits. Recently discovered bituminous coal reserves at Slany were estimated to contain 150 million tons.[34]

The Slany coal deposits will be handed over to the Kladno mining concern by the middle of 1978 to develop the two pilot mines at a depth of over 1,200 meters.

The projected Slany mine is to be the deepest bituminous coal mine in Czechoslovakia. This mine is expected to produce 2.5 million tons of coal per year after 1990.[35] Plans for mining coal in the Slany area are focused in particular on three seams: The Dolín, Luben, and main Kladno seams. Coal seams at Slany are situated in complicated geological and hydrogeological conditions.

Coal reserves at the Slany site guarantee that the working life of coal mines in this area will be approximately 45 years. During 1977-85, other bituminous coal deposits are also to be developed.

In 1977, about 650 Polish workers and engineers were working in Czechoslovia on the construction of a coal transloading station situated near Litomerice (Northern Bohemia). When the station is completed, it will load 35,000 tons per day of coal into barges for the Chvaletice power station and other customers along the Elbe River.[36]

In 1977, 73% of the brown coal output came from the Northern Bohemian Basin. This basin, together with the neighboring Sokolov Basin, represents the largest mining area in Czechoslovakia. Output from the Sokolov Basin was 19.8 million tons (21.8% of total output) in 1977 and is to remain unchanged, whereas output from the Northern Bohemian Basin is expected to rise 66.4 million tons in 1977 to more than 70 million tons in 1980. In the following years, the output of brown coal is to increase to 75 million tons per year.[37] The Northern Bohemian Basin is the only developing basin in Czechoslovakia. In 1980, this basin is to meet 44% and in 1990 about 37% of all energy needs of the country. The Northern Bohemian coal basin is the main supplier of fuel to the growing number of Czechoslovak power stations. The problems of declining coal quality are compounded by greater air pollution by fly ash and sulfur dioxide. The Maxim Gorkiy mine, with a planned annual capacity of 16 million tons of raw brown coal, is the largest open pit in this basin.

In 1978, production of brown coal from four open pits (Bzezno, Merkur, Maxim Gorkiy, and Erika) is to increase 5 million tons. Development of the Vrsany surface mine naer Most, with an annual capacity of 6 million tons, began in 1977.

In 1977, the brown coal and lignite open pits were 100% mechanized; approximately 24% of the coal was mined by power shovels and 76% by rotary excavators. About 21% of the overburden was removed by power shovels, 66% by rotary excavators, and 13% by chain bucket excavators.

Consumption of brown coal in 1976 was as follows: Electric powerplants 48.3%, steam for heating and industrial use 24.6%, railroads 0.8%, households 9.7%, and other 6.6%.

During the 1976-1980 plan period, it is planned to invest Kcs26 billion, a 60% increase over that of 1971-1975, in development of the coal industry. Kcs5 billion alone is to be invested during this period to procure new machinery for brown coal surface mines.

Natural Gas.—Production of natural gas in 1977 was about 1.0 billion cubic meters. Gasfields are located mostly in Southern Moravia (the northern part of the Vienna Basin). In 1977, natural gas imports totaled 7.2 billion cubic meters of which 5.2 billion cubic meters was received from the U.S.S.R. In 1976, Czechoslovakia signed an agreement with Iran that provided for annual imports of 3.6 billion cubic meters of gas for 20 years, starting in 1981. Czechoslovak-Soviet agreements, under which Iranian natural gas will flow by way of the U.S.S.R. to Czechoslovakia and Western Europe, were expected to be signed in Prague in February 1978. The agreements also provide for the construction of the third gas transit pipeline across Czechoslovak territory with a capacity of 17.5 billion cubic meters per year. The third pipeline is to be completed in 1984. With an overall pipeline capacity of about 53 billion

Digitized by Google

cubic meters per year of natural gas, Czechoslovakia will become the largest and most significant transporter of natural gas in Europe.

In 1977, Czecholovakia continued to participate in the CMEA project for development of the Orenburg gasfields and building the main pipeline (named Soyz) from Orenburg to the western frontier of the U.S.S.R. The gas obtained in payment for this project will account for most of the increase in natural gas resources in 1979 and 1980.

In 1977, the gas transit pipeline carried about 22 billion cubic meters of Soviet natural gas to Western Europe and Czechoslovakia. The gas pipeline system on Czechoslovak territory totaled 2,238 kilometers.[38]

In 1977, the southern section of the second string of the gas transit pipeline went into operation. In September, an underground gas storage with a capacity of 200 million cubic meters was handed over for use at Lab, near Bratislava.

Petroleum.—Production of crude oil in Czechoslovakia is insignificant and has been declining throughout the 1970's while its consumption has increased steadily. Total proved crude oil reserves were estimated in 1964 at only 2.5 million tons. Czechoslovakia's oil comes mainly from the Gbely and Hodonín fields.

In 1977, Czechoslovakia processed 17.5 million tons of U.S.S.R. crude oil, a 3.5% increase over that of 1976. Soviet deliveries made up some 96% of total crude oil imports. In 1978, crude oil and petroleum products imports from the U.S.S.R. are to increase 4.1% over those of 1977. The annual growth rate of soviet deliveries of crude oil to Czechoslovakia dropped from 13.5% in 1971 to 4.1% in 1977.

In 1977, Czechoslovakia participated in the financing and construction of an oil pipeline running from an Adriatic seaport in Yugoslavia to Czechoslovakia. Czechoslovak organizations were in charge of the construction of a 105-kilometer section across Hungary. The project includes the delivery of pipes, the assembly and laying of pipes, and the construction of four pumping stations and four crude oil storage tanks.[39] The Adriatic line is expected to be operational in 1979, when Czechoslovakia is to receive 5 million tons of crude oil from Africa and the Middle East.

The Czechoslovak refining industry is to be capable of processing 21 million tons of crude oil in 1980: Approximately 6 million tons in Litvínov, 3 million tons in Kralupy, 1 million tons in Pardulice, 300,000 tons in Ostravá, 200,000 tons in Kolin, approximately 9 million tons in the Bratislava Slovnaft enterprise, and 1.5 million tons in Vojany.[40]

A 1976 agreement with Hungary provided for joint oil-prospecting operations along the Danube River at depths of up to 4,000 meters.

The Mineral Industry of Denmark and Greenland

By Joseph B. Huvos[1]

Denmark and Greenland have few mineral resources and must import most fuels and minerals. Production includes some crude oil in the North Sea, diatomite in Denmark, and lead, and zinc in Greenland.

Denmark and Greenland's economy was sluggish in 1977; inflation was 9% and unemployment was 6.5%. The country's balance-of-payments deficit was covered by public borrowing abroad.

The gross national product (GNP) of Denmark and Greenland, reported as a total, was about $41.5 billion in 1977.[2] [3] The Contribution of the principal sectors of the mineral industry to the GNP in 1976 and 1977 and average employment in 1977 are shown in the following tabulation:

Sector	Contribution to GNP (millions)			Average 1977 employment (thousand persons)
	1976[r]	1977	Percent increase	
Base metals	$29	$31	6.9	6.4
Nonmetals	74	81	9.5	17.9
Chemicals	221	228	3.2	21.4
Total	324	340	4.9	45.7

[r]Revised.

Source: Danmarks Statistisk (Copenhagen). Economic Trends. No. 1, April 1978, pp. 28, 32.

Important events in the mineral industry of Denmark and Greenland included two oil and gas finds in the North Sea, continued construction of an iron ore mine in Greenland, and completion of an unsuccessful oil drilling season in Greenland's offshore waters.

PRODUCTION

In 1977, production of most mineral products increased. Production of selected mineral commodities in 1975-77 is detailed in tables 1 and 2.

Table 1.—Denmark: Production of mineral commodities

(Thousand metric tons unless otherwise specified)

Commodity	1975	1976	1977[p]
METALS			
Iron and steel:			
Iron ore (less than 42% iron) gross weight	13	8	5
Metal:			
Crude steel[2]	559	722	686
Semimanufactures	[r]438	552	[3]560
Lead metal, secondary (including alloys)[1]	13	19	23
NONMETALS			
Cement, hydraulic[1]	2,237	2,355	2,309
Chalk[1] thousand tons	82,920	89,719	124,133
Clays: Kaolin, crude and washed[e] do.	23,000	23,000	23,000
Diatomaceous materials:[e]			
Diatomite	21	21	25
Moler	[r]230	[r]230	230
Fertilizer materials, manufactured, gross weight:[1]			
Nitrogenous	47	59	86
Phosphatic	417	548	428
Mixed and unspecified	215	336	358
Lime, agricultural, and quicklime[1]	166	231	173
Salt[1] thousand metric tons	244	349	314
Stone, sand and gravel:[1]			
Dimension stone[4] thousand cubic meters	34	35	39
Crushed and broken stone:[5]			
Limestone:			
Agricultural	2,028	1,887	1687
Other	267	278	284
Other thousand cubic meters	[e]10	11	10
Sand:			
Industrial do.	1,461	1,135	1,161
Other do.	666	786	626
MINERAL FUELS AND RELATED MATERIALS			
Coke, gashouse	83	70	[e]70
Peat, agricultural [1]	35	39	40
Petroleum:			
Crude thousand 42-gallon barrels	1,327	1,492	3,285
Refinery products:			
Gasoline do.	12,809	11,863	11,943
Jet fuel do.	28	1	72
Kerosine do.	722	866	775
Distillate fuel oil do.	23,964	[e]25,081	25,588
Residual fuel oil do.	16,515	16,242	14,992
Lubricants do.	30	30	--
Unspecified do.	3,443	3,577	3,839
Refinery fuel and losses do.	2,933	3,615	4,465
Total do.	60,444	61,275	61,674

[e]Estimate. [p]Preliminary. [r]Revised.

[1]Sales.

[2]Includes shipyards production of steel castings.

[3]Excludes steel forgings.

[4]Includes only granite and gneiss; quantity of other dimension stone is not reported, but sales value was $209,878 in 1975, $332,341 in 1976, and $302,838 in 1977.

[5]Partial figures; exclude quartz and quartzite for which quantities are not reported. However, sales value was $203,961 in 1975, $377,833 in 1976, and $356,143 in 1977.

[6]Excludes flint valued at $2,602,938.

Table 2.—Greenland: Production of mineral commodities

(Metric tons)

Commodity[1]	1975	1976	1977[p]
Lead, mine output, metal content	24,300	27,000	28,800
Zinc, mine output, metal content	84,700	81,000	76,600

[p]Preliminary.

[1]In addition to the commodities listed, a variety of crude construction materials (common clay, sand and gravel, and stone) is undoubtedly also produced, but output is not reported and available information is inadequate to make reliable estimates of output levels.

TRADE

In 1977, there was no important change in the trade pattern of Denmark and Greenland. Imports of fossil fuels amounted to about 17% of all imports, while exports of mineral products remained insignificant. The main trading partners were the countries of Europe. Denmark's commodity trade in 1975 and 1976 is shown in tables 3 and 4.

Major items of mineral imports from the United States were iron and steel semimanufactures, nonferrous metals, potash, coal, and petroleum products. Mineral exports to the United States included iron and steel, base metals, and industrial minerals. United States-Denmark and Greenland trade in 1976 is shown in table 5.

Table 3.—Denmark: Exports of mineral commodities

(Metric tons unless otherwise specified)

Commodity	1975	1976	Principal destinations, 1976
METALS			
Aluminum:			
Bauxite and concentrate	18,344	21,802	France 6,993; Belgium-Luxembourg 4,917; Netherlands 2,157; Thailand 2,110.
Oxide and hydroxide[1]	r315	64	United States 22; West Germany 15; United Kingdom 12.
Metal including alloys:			
Unwrought, including scrap	r7,562	9,447	West Germany 4,927; Sweden 1,682; Belgium-Luxembourg 1,289.
Semimanufactures	9,195	11,526	Sweden 5,639; West Germany 1,338.
Antimony metal including alloys, all forms	3	6	Norway 5; Venezuela 1.
Chromium, chromite	2	2	NA.
Cobalt metal including alloys, all forms	2	1	All to Sweden.
Copper metal including alloys:			
Scrap	7,841	8,849	West Germany 8,228.
Unwrought	556	821	Sweden 472; West Germany 303.
Semimanufactures	3,574	4,392	United Kingdom 1,858; Sweden 947; Finland 651; West Germany 480.
Iron and steel:			
Ore and concentrate	12,056	8,442	West Germany 4,662; United Kingdom 2,090; Netherlands 930.
Metal:			
Scrap	90,968	115,673	West Germany 52,231; Norway 16,924; United Kingdom 16,349; Sweden 12,844.
Pig iron, including cast iron	538	104	Sweden 71.
Sponge iron, powder, shot	r136	192	Mainly to West Germany.
Ferroalloys	10	17	Mainly to Norway.
Steel, primary forms	r1,297	3,010	Netherlands 896; United Kingdom 894; Norway 673.
Semimanufactures:			
Bars, rods, angles, shapes, sections	101,221	97,202	Sweden 35,152; West Germany 30,257; Norway 11,797.
Universals, plates, sheets	140,161	195,158	Sweden 102,495; West Germany 44,804; Norway 23,630.
Hoop and strip	11,183	16,046	Sweden 15,592.
Rails and accessories	---	3,076	Mexico 2,339.
Wire	7,047	5,862	Sweden 2,285; Finland 1,143; Norway 696.
Tubes, pipes, fittings	r30,524	36,376	Sweden 21,038; West Germany 4,207.
Castings and forgings, rough	19,784	16,589	Sweden 7,237; West Germany 4,549; Norway 2,540.
Total	r309,920	370,309	
Lead:			
Ore and concentrate	245	633	West Germany 610.
Oxide	92	39	West Germany 25; Kuwait 7; Saudi Arabia 7.
Metal including alloys:			
Scrap	402	468	West Germany 372; Sweden 60.
Unwrought	5,293	10,919	U.S.S.R. 2,000; Norway 1,902; Sweden 1,681.
Semimanufactures	279	235	Finland 144; Norway 28.
Magnesium metal including alloys, all forms	r117	113	West Germany 67; Netherlands 16.
Manganese oxide	169	66	Sweden 62.
Molybdenum metal including alloys, all forms	r145	163	West Germany 86; United Kingdom 53.
Platinum-group metals and silver:			
Waste and sweepings, thousand troy ounces	1,343	1,360	United Kingdom 478; West Germany 443; Netherlands 238; Sweden 140.
Metals including alloys:			
Platinum-group, do.	3	(2)	Mainly to Thailand, Sweden, and Finland.
Silver, do.	267	707	Sweden 254; Finland 183; Norway 108; Netherlands 96.

Salt	r122,234	205,686	West Germany 86,271; U.S.S.R. 33,290; Italy 30,145; Poland 27,774.
Stone, sand and gravel:			
Dimension stone:			
Crude and partly worked:			
Calcareous	r3,219	4,472	Sweden 3,125; Italy 1,202.
Slate	9,231	10,753	Norway 5,118; West Germany 2,444; Sweden 1,820.
Other (granite, gneiss, etc.)	17,163	152,974	Sweden 136,423; Norway 16,335.
Worked, all types	r42,975	50,610	Portugal 15,768; West Germany 12,275; Sweden 11,884; Poland 5,265.
Dolomite, chiefly refractory grade	22,169	29,265	Norway 20,939; United Kingdom 2,990.
Gravel and crushed rock	588,312	676,928	Sweden 620,472.
Limestone (except dimension)	182,691	198,286	Sweden 109,787; United Kingdom 44,491; Norway 30,170.
Quartz and quartzite	r6,638	7,985	Sweden 3,529; West Germany 2,385; Norway 1,858.
Sand, excluding metal bearing	148,864	170,108	Belgium-Luxembourg 109,125; Norway 48,702.
Sulfur:			
Elemental, all forms	r69,675	62,651	West Germany 61,152.
Sulfur dioxide and sulfuric acid	r2,438	4,669	West Germany 3,980.
Talc, steatite, soapstone, pyrophyllite	9,365	11,525	Norway 5,737; West Germany 3,338.
Other:			
Crude	r50,115	50,341	West Germany 41,408; Sweden 4,955.
Slag, dross, and similar waste, not metal bearing	5,823	7,877	West Germany 4,466; United Kingdom 2,362.
MINERAL FUELS AND RELATED MATERIALS			
Asphalt and bitumen, natural	707	619	United States 361; West Germany 192.
Carbon black	r3,064	3,995	West Germany 1,348; Sweden 1,043; United Kingdom 651; United States 357.
Coal and coke, including briquets thousand tons	r4,264	4,317	Poland 3,168; U.S.S.R. 640.
Gas, hydrocarbon, liquefied do.	91	116	United Kingdom 37; West Germany 29; Netherlands 15; Sweden 13.
Peat, including peat briquets and litter	r14,925	18,534	Sweden 12,349; U.S.S.R. 2,987.
Petroleum:			
Crude and partly refined thousand 42-gallon barrels	r58,019	55,793	Iran 17,003; Saudi Arabia 8,409; U.S.S.R. 6,905; Nigeria 5,468.
Refinery products:			
Gasoline do.	r9,835	10,294	Netherlands 2,692; United Kingdom 2,027; Belgium-Luxembourg 1,827; Sweden 1,449.
Kerosine and jet fuel do.	r5,840	8,019	Netherlands 3,175; Belgium-Luxembourg 1,376; United Kingdom 1,132.
Distillate fuel oil do.	28,236	32,279	United Kingdom 10,795; Belgium-Luxembourg 4,665; U.S.S.R. 3,994; Netherlands 3,880.
Residual fuel oil do.	32,348	27,279	Netherlands 7,592; Sweden 6,637; Norway 2,535.
Lubricants do.	r600	757	United Kingdom 232; West Germany 190; Netherlands 178; Sweden 84.
Mineral jelly and wax do.	r104	124	West Germany 83.
Other:			
Nonlubricating oils, n.e.s. do.	89	--	
Petroleum coke do.	2	2	Mainly from West Germany.
Bitumen and other residues do.	1,173	1,238	Netherlands 639; West Germany 431; Sweden 119.
Bituminous mixtures, n.e.s do.	11	10	West Germany 6; United Kingdom 2.
Total do.	r78,238	80,002	
Mineral tar and other coal-, petroleum-, or gas-derived crude chemicals	13,378	24,709	Sweden 8,064; Norway 4,365; West Germany 3,147; United States-Puerto Rico 2,522.

rRevised. NA Not available.
[1]Not including synthetic corundum.
[2]Includes spiegeleisen, gut, sponge, powder, and shot of iron and steel.
[3]Including wire rod.

COMMODITY REVIEW

DENMARK

Metals.-*Iron and Steel.*—Production of iron and steel was based mainly on scrap, supplemented with small quantities of domestic iron ore and roasted pyrite. Det Danske Stålvalsevaerk A/S (DDS), with plants located at Frederiksvaerk and Helsingør on Sjaelland Island north of Copenhagen and a virtually all-electric steelmaker, remained the country's main iron and steel producer. The company's principal products included heavy plates and merchant bars.

Nonmetals.—*Cement.*-In 1977, A/S Alborg-Portland-Cement Fabrikk, owned by F. L. Smidth & Co. A/S, operated the country's three cement plants with a total capacity of 2.67 million tons per year, including a 2.2-million-ton-per-year plant and a 185,000-ton-per-year plant (temporarily out of production) at Rördal near Ålborg, and a 285,000-ton-per-year plant at Lindholm near Nörresundby. Another company plant at Dania near Mariager continued to be used to calcine bauxite imported from Guyana.

Diatomite.—Denmark was after the United States and the U.S.S.R., the world's third largest diatomite producer in 1977, with a production of 255,000 tons. Major Danish producers were Skarrehage Molervaerk A/S, Branden Molervaerk A/S, Danske Moler Industri A/S, and Molervaerk Ludolph Struve A/S.[4]

Moler, the local name for diatomite, is a tertiary clayey diatomaceous earth found in Denmark and is mined mainly on Fur and Mors Islands.

Fertilizer Materials.—In 1977, Superfos A/S, the country's largest fertilizer maker, continued construction of a 550,000-ton-per-year ammonia plant at Brunsbüttel in Schleswig-Holstein State, Federal Republic of Germany. Veba-Chemie AG, of the Federal Republic of Germany, was the Superfos associate in this project. There was no ammonia plant in Denmark itself.

Mineral Fuels.—In 1977, Denmark remained almost completely dependent on imported fuels, with only nominal crude oil and hydroelectric power production. Use of alternate sources of energy such as nuclear power and natural gas remained under discussion.

Table 6 shows the supply and apparent consumption of fuels and power in Denmark and Greenland in 1976 and 1977.

Table 6.—Denmark and Greenland: Supply and apparent consumption of fuels and power for 1976 and 1977

(Million tons of standard coal equivalent[1])

	Total energy	Coal and coke	Petroleum and refinery products[2]	Hydroelectric power[3]
1976:				
Production[4]	0.3	--	0.3	--
Imports	32.8	4.4	28.1	0.3
Exports	4.1	--	3.9	.2
Apparent consumption	29.0	4.4	24.5	.1
1977:[p]				
Production[4]	.8	--	.8	([5])
Imports	35.1	5.7	29.1	.3
Exports	3.4	--	3.2	.2
Apparent consumption	32.5	5.7	26.7	.1

[p]Preliminary.
[1]1 ton standard coal equivalent=7,000,000 kilocalories.
[2]Includes some liquid natural gas imports.
[3]Includes foreign trade of all electricity.
[4]Includes only primary energy.
[5]Less than 1/2 unit.

Petroleum and Natural Gas.—Dan, Denmark's only operational oilfield in 1977, was located 200 kilometers west of Esbjerg in 41 meters of water. It had three steel drilling platforms from which the production was tanker-loaded at a rate of 700,000 tons per year. Crude oil production was to decrease in 1978 when Denmark's three production wells are to be redrilled.

Estimated recoverable oil reserves in the Danish sector of the North Sea were 18 million tons at the end of 1977.[5]

The Danish Underground Consortium (DUC), the only operator in the Danish sector of the North Sea, undertook exploration in the vicinity of the Dan Field and made two oil discoveries (Ruth and Adda) and one gas discovery (Vagn). DUC filed an application to develop the Gorm Field, 27 kilometers northwest of Dan, but was refused because production would have involved flaring of the gas produced.

In 1977, Denmark's petroleum refining capacity remained at 11.6 million tons. Major companies involved in refining were Gulf Oil Refining A/S, Dansk Esso A/S, and A/S Dansk Shell, with refineries at Stigsnaes, Kalundborg, and Fredericia, respectively.

GREENLAND

In 1977, Greenland produced lead and zinc concentrates and shipped some crude cryolite from existing stocks.

Metals.—*Iron Ore.*—Preparations continued to mine iron ore at Isua, located on Godthaab Fjord. The project is a joint venture involving Kryolitselskabet Øresund A/S and Marcona Corp. of New York.

Lead and Zinc.—In 1977, for the fourth consecutive year, Greenex A/S operated the Black Angel mine at Marmorilik on the western coast of Greenland under a concession from Denmark's Ministry for Greenland. The production of 553,000 tons of ore contained 15.1% zinc and 6.1% lead. Concentrates were sold to various Western European smelters.[6]

Exploration by surface and underground drilling was successful in maintaining ore reserves equivalent to 6 years' production, or 3.6 million tons of ore containing 4.0% lead, 12.4% zinc, and 1 troy ounce per ton of silver. Mineralization found on nearby Uvkussigsat Peninsula in 1976 was mapped in 1977.

Nonmetals.—*Cryolite.*—Shipping of cryolite ore from stock at the depleted mine at Ivigtut continued at a reduced rate and with lower grade. Shipments were processed at the concentrating plant in Denmark.

Mineral Fuels.—Petroleum.—The second season of offshore exploratory drilling off the west coast of Greenland was closed, resulting in four dry wells. Denmark's Ministry for Greenland received no applications for offshore drilling near Greenland for 1978. In 1977, unsuccessful exploration was focused in areas offshore Holsteinsborg and Sukkertoppen.

Uranium.—In 1977, uranium reserves in the Kvanefjeld Mountains near Narssaq in southern Greenland almost tripled as a result of further drilling carried out during the summer months. Known reserves of uranium are now put at 15,700 tons[7] and estimated reserves at another 10,000 tons. The average grade of the ore is 300 grams of uranium per ton. One-third of the drilling cost of $1.5 million was provided by the European Economic Community in exchange for a share in future production.

The Mineral Industry of Egypt

By Candice Stevens[1]

Egypt's mineral industry contributed approximately 17% to the 1977 gross national product (GNP), estimated at $17 billion.[2] Increased petroleum revenues, in addition to greater earnings from augmented production of phosphate rock, steel, and aluminum, were expected to make the mineral sector a more significant contributor to the nation's economy within the next few years. The 5-year plan (1976-80) forecast that the value of the industrial and mineral sectors would grow 12% by 1980. Approximately $870 million was allocated to the development of this sector, with the major portion devoted to the Helwân iron and steel complex, the Nag' Hammadi aluminum plant, the Abu Tartûr phosphate deposits, and the fertilizer and cement industries.

At yearend, Egypt's medium and long term debt was approximately $12 billion. Egypt continued as the largest recipient of U.S. aid, which totaled $900 million in fiscal year 1977. A loan of $1.5 billion was received from the Gulf Organization for Development in Egypt (GODE), established in 1976 by Saudi Arabia, Kuwait, the United Arab Emirates, and Qatar to provide project support and assist in remedying the balance-of-payments deficit. The Consultative Group for the Arab Republic of Egypt, composed of 15 countries and agencies including the United States, Japan, Western European countries, the International Bank for Reconstruction and Development (IBRD), and the International Monetary Fund (IMF), held its first meeting in May 1977. The Consultative Group, which was formed to coordinate Egyptian aid programs, sought to identify specific projects in the 5-year plan for which loans could be made.

In 1977, further revisions were enacted in Egypt's Investment Law No. 43 to attract greater foreign participation in development. New provisions minimized restrictions on holding and using foreign exchange, altered the fixed exchange rate system, and granted income tax exemptions on Arab and foreign investments. Also under consideration were revisions to the mining code to encourage foreign investment under partnership agreements with the Government. In 1976, private Egyptian companies for the first time were given leases for mineral exploration and development of small mineral deposits.

The Egyptian Geological Survey Organization was responsible for developing proposals for joint venture mineral exploration and/or development projects. In 1977, the U.S. Geological Survey continued its general mineral resource identification program. Egypt was to initiate a pilot study of the Wadi Natrum area northwest of Cairo, where a large freshwater reservoir had been identified beneath the Western Desert.

Work continued on deepening and widening the Suez Canal, which was reopened in June 1975 following an 8-year closure brought about by the 1967 Arab-Israeli war. The expansion program, undertaken by an international group of contractors at a cost of $1 billion, was to enable ships up to 150,000 tons laden and 300,000 tons in ballast to transit the Canal. In 1977, an average of 60 ships per day used the Canal, 40% of which were oil tankers. The Suez Canal was expected to earn $1 billion in transit fees by 1980.

A 20-year port development plan was proposed to ease congestion at Egypt's overloaded terminals and to accommodate increased mineral exports. The ports at Suez,

Digitized by Google

Ismailia, and Port Said were to undergo renovation and expansion. New industrial and mineral ports were to be constructed at Dekhela, Port Safâga, and Hamrawein.

[1]Egypt also produces some sodium carbonate, but output is not reported and available information is inadequate to make reliable estimates of output levels.

[2]Previously reported incorrectly as including vermiculite.

[3]Quantity reported is valued at $2,047,951; excludes quantity valued at $305,025.

PRODUCTION AND TRADE

Production of petroleum, Egypt's major mineral commodity, increased 26% from 120 million barrels in 1976 to 151 million barrels in 1977. Production of refined petroleum products and natural gas also evidenced increases in 1977. Iron ore output rose as the Bahariya Oasis deposits were brought into full production. Production of steel at the Helwân iron and steel complex and of aluminum at the Nag' Hammadi aluminum complex both increased in 1977 as technical difficulties at the two plants were remedied. Although startup of new phosphate mines was delayed until 1978, phosphate rock production registered a 20% increase. Production of two other key mineral products, cement and fertilizer, was expected to greatly increase over the next few years as new plants were brought on-stream. Egypt also produced smaller quantities of manganese, barite, gypsum, talc, and salt. Minerals produced in Egypt are shown in table 1.

Egypt's overall balance-of-trade deficit rose to approximately $3.5 billion in 1977, as increased petroleum exports were unable to offset rising imports of both foodstuffs and capital goods. Egypt became a consistent net exporter of oil in 1974 and sought to earn more than $1 billion through oil exports by 1980. In 1977, petroleum exports were valued at $729 million and imports at $180 million, giving Egypt a $549 million surplus on its oil account. In addition to petroleum, Egypt's other important mineral exports were phosphate rock and aluminum. Both the Suez Canal and the Suez-Mediterranean (SUMED) pipeline assumed increased importance as foreign exchange earners in 1977. Egypt's trade in mineral commodities is shown in tables 2 and 3.

COMMODITY REVIEW

METALS

Aluminum.—Production of aluminum ingot at the Nag' Hammadi complex increased from 55,000 tons in 1976 to approximately 89,000 tons in 1977. The plant, situated 200 kilometers west of Port Safâga on the Red Sea, began production at yearend 1975. Expansion to an annual capacity of 160,000 tons was scheduled for 1980. Alumina was imported from Australia in 1977. Aluminum ingot was exported to Western European countries and Japan.

Arab Aluminum Co., a joint venture of Egyptian, Kuwaiti, and U.S. investors, began production at its plant in Ismailia in October 1977. The aluminum-fabricating facility was to produce a variety of industrial and consumer products for domestic use and export.

Copper.—Copper-nickel deposits in the Eastern Desert were under investigation by the Egyptian Geological Survey Organization. Reserves at Um-Simiuki were previously estimated at 70,000 to 80,000 tons of ore containing 3% to 4% copper.

Iron and Steel.—Production of iron ore, which came primarily from the Bahariya Oasis, totaled 1.4 million tons in 1977. Smaller iron ore deposits at Aswan were being phased out as the Bahariya Oasis deposits, located 300 kilometers southwest of Helwân, were brought into full operation. Production capacity at the Bahariya Oasis was 1.5 million tons per year, to be in-

Digitized by Google

creased to 3.5 million tons per year by the early 1980's. Reserves were estimated at 200 million tons of ore containing 54% iron and 3% silica. A 350-kilometer railroad was completed during the year linking the Bahariya Oasis deposits with Helwân.

Iron ore production was used by the Helwân iron and steel complex, which produced approximately 880,000 tons of crude steel and steel products in 1977. Operational difficulties, including equipment breakdowns and a lack of spare parts, a shortage of trained technicians, and irregularities in the supply of coking coal, prevented the plant from reaching its targeted output of 1.5 million tons of steel. Steps were being taken to construct onsite workshops for maintenance and supply of spare parts, to establish a metallurgical institute for training engineers, and to double the plant's production of coke. In addition, the Government contracted a Japanese consortium to prepare a feasibility study for overall modernization of the Helwân complex, which began production in 1958.

A direct-reduction steel plant was to be built at Dekhela by a joint venture including the General Organization for Industrialization (50%), C. Itoh & Co., Ltd. (Japan) (25%), Korf Stahl A.G. (Federal Republic of Germany) (15%), and Cia. Vale do Rio Doce (Brazil) (10%). The $380 million plant was to use iron ore pellets imported from Brazil and natural gas from the Abu Qir field. Production, to begin in 1981, was to total 1.6 million tons of steel per year.

Manganese.—Egypt produced approximately 3,800 tons of manganese from the Wadi Meialik deposits in the Eastern Desert. This was the only manganese-producing area of Egypt, which had previously mined 200,000 tons of manganese per year at Umma Bogma on the Sinai Peninsula. Reserves at Umma Bogma, which came under Israeli control in 1967, were estimated at 2 million tons of 21% manganese ore.

Uranium.—Feasibility studies were being conducted on the production of uranium from the Abu Tartûr phosphate deposits and the uraniferous black sands along the Mediterranean coast and the Nile Delta. The phosphate deposits at Abu Tartûr were estimated to contain 100,000 tons of uranium or 100 grams of uranium per ton of ore. Monazite in the black sands was estimated to contain 26,000 tons of uranium.

NONMETALS

Barite.—Egypt quarried 746 tons of barite in 1977 for use as a weight material in petroleum drilling muds. Barite was quarried at two main sources, Gebel Hudi near Aswan and Wadi Elba at the southeastern border of Egypt and Sudan. It was transported by railroad to Cairo where it was fine-ground and bagged. Local deposits of barite were considered to be far in excess of production needs.

Cement.—In 1977, Egypt produced 3.3 million tons of cement for local use. Cement production capacity was rated at approximately 4 million tons concentrated in four plants, as follows: Torah Portland Cement Co., 1.4 million tons; Helwân Portland Cement Co., 1.4 million tons; Alexandria Portland Cement Co., 500,000 tons; and National Cement Co. at Assiut, 700,000 tons.

Annual imports of cement were about 1 million tons. To meet a projected domestic cement demand of 10 million tons, plans were made to expand the Alexandria and Assiut plants and to construct new facilities at Torah, Suez, and Nag' Hammadi.

Fertilizer Materials.—Approximately 660,000 tons of nitrogenous fertilizer and 520,000 tons of phosphatic fertilizer were produced in 1977. Egypt continued to be heavily dependent on imported fertilizer and needed to remedy the reduced silt deposition in the Nile Valley since the commissioning of the Aswan Dam. Imports were expected to decline in 1978 owing to the startup of new facilities.

Ammonium nitrate based fertilizers made up the greater part of Egyptian output. The three producing plants were operated by Soc. el-Naşr d'Engrais et d'Industries Chimiques at Suez, El Naşr Co. for Manufacture of Coke & Chemicals at Helwân, and Egyptian Chemical Industries (KIMA) at Aswan. Construction continued on new plants at Talkha, which would use natural gas feedstock from the Abu Madi field, and at Alexandria, which would be supplied by natural gas from the Abu Qir field. The plants were both operated by Soc. el-Naşr d'Engrais et d'Industries Chimiques and would each produce 260,000 tons per year of ammonia and urea by 1978. KIMA also planned a joint venture with Iran for construction of a nitrogenous fertilizer complex at Shuqeir on the Red Sea.

Phosphatic fertilizer was produced by the Abu Zaabal Fertilizer & Chemical Co. plant at Abu Zaabal, the Kosseir Phosphate Co. plant at Kosseir, and the Soc. Financière et Industrielle d'Egypte S.A. plants at Assiut and Kafr-el-Zaiyat. Phosphatic fertilizer

Digitized by Google

production capacity was rated at 535,000 tons per year. Abu Zaabal's new triple superphosphate plant was expected to come onstream in 1979 with a capacity of 170,000 tons per year. Cremer and Warner (United Kingdom) was contracted to provide technical assistance for the construction of the plant and handling facilities. Phosphate was to be obtained from the West Sabaya mine in the Nile Valley.

Phosphate Rock.—Phosphate rock production increased from 390,000 tons in 1976 to 470,000 tons in 1977. Approximately 50% of production was exported. Phosphate operations were nationalized in 1956, and mining and marketing was under the control of the Egyptian General Organization for Geological Research and Mining (GOGRM). Phosphate rock production was to be greatly increased in the next 5 years through exploitation of deposits at Hamrawein, Shagila, Abu Tartûr, and El Mahâmid. Egypt's three main areas of phosphate rock deposition were as follows:

1. Red Sea Coast.—Once the center of phosphate mining activity, the Port Safâga and Kosseir mines in the Red Sea area of the Eastern Desert were expected to be depleted by 1980. However, the Hamrawein deposits were under development with Romanian technical assistance. Production at the rate of 1.2 million tons per year was to begin in 1978. Reserves were estimated at 400 million tons. Plans were also under study to exploit the Shagila deposits at a rate of 600,000 tons per year. The People's Republic of China was to finance part of the development cost of Shagila, where reserves were estimated at 300 million tons.

2. Nile Valley.—Estimated reserves in the Nile Valley region between Isna and Idfu north of Aswan were 300 million tons. Production at the El Mahâmid mine was to be increased to 450,000 tons per year. The West Sabaya operation was also to be expanded from 120,000 tons to 500,000 tons per year to supply the Abu Zaabal fertilizer complex.

3. Western Desert.—The phosphate deposits at Abu Tartûr, estimated to contain reserves of 1 billion tons with an average P_2O_5 content of 25.6%, were to be developed by 1985. The engineering design contract was awarded during the year to Sofremines of France and Alusuisse of Switzerland. Abu Tartûr was expected to yield 10 million tons of ore per year to be processed into 7 million tons of phosphate concentrate. Infrastructure requirements included a 600-kilometer railroad to Port Safâga and new port facilities for handling increased phosphate exports.

Gypsum.—Both gypsum and limestone were widely distributed in Egypt and quarried as a source of building stone and raw material for manufacturing cement. Approximately 509,000 tons of gypsum was produced in 1977. Gypsum was quarried at many places associated with anhydrite—on the Gulf of Suez, at Ballah in the Suez Canal area, and at Ras Matarma and Ras Mallap on the Sinai Peninsula. During 1977, a joint venture was established by Egypt and Kuwait to mine gypsum deposits discovered in the Western Desert near Sidi Abdel Rahman. Reserves were estimated at 300 million tons. Approximately 80% of production was to be exported.

MINERAL FUELS

Coal and Coke.—Coke output from the coke and basic chemicals factory at Helwân increased to 694,000 tons in 1977. Further expansion was planned. Egypt has imported all of its coal requirements since the Maghara coal mines on the Sinai Peninsula were closed in 1967. Reserves at the Maghara deposit were estimated at 50 million tons and had previously been mined at the rate of 67,000 tons per year.

Natural Gas.—Egypt marketed approximately 14 billion cubic feet of natural gas in 1977, of which 39% was used by producers, 15% was sold for fuel or raw material, and 46% was used for oilfield reinjection. Natural gas reserves were estimated at 5 trillion cubic feet and were concentrated in four major fields. The Abu Madi, Abu Qir, and Abu al-Gharadiq fields were under development, but there were no immediate plans to utilize gas associated with oil in the El Morgan field in the Gulf of Suez.

In 1977, the Egyptian General Petroleum Authority (EGPA) assumed full ownership of gas reserves at Abu Madi, previously operated by a joint venture of Egyptian General Petroleum Corp. (EGPC) (EGPA's predecessor) and the Italian firm Ente Nazionale Idrocarburi (ENI). Production was to reach a rate of 150 million cubic feet of gas per day by 1978. Output was distributed to local industry in the Cairo area and was to supply the new Talkha fertilizer complex. Reserves were estimated at 1.4 trillion cubic feet.

The Abu Qir field, located offshore Alexandria, was operated by Western Desert Operating Petroleum Co. (WEPCO), a joint venture of EGPA and Phillips Petro-

Digitized by Google

leum Co. Production was to begin in 1978 at the rate of 124 million cubic feet of gas per day, to be distributed to the Alexandria industrial area. Reserves were estimated at 1 trillion cubic feet.

A 300-kilometer pipeline linking the Abu al-Gharadiq field with Torah and Helwân was inaugurated in April 1977. The field was operated by Fayoum Petroleum Co. (FAPCO), a joint venture of EGPA and Amoco Egypt Oil Co. Production at the rate of 160 million cubic feet of gas per day was to fuel steel and cement plants. Reserves were estimated at 2.2 trillion cubic feet.

Petroleum.—*Production.*— Petroleum production increased from an average of 329,000 barrels per day in 1976 to 413,500 barrels per day in 1977. Targeted output was 1 million barrels per day by 1980. EGPA supervised all exploration, production, refining, and marketing of petroleum and its products.

Approximately 70% (290,000 barrels per day) of Egypt's petroleum output was produced by Gulf of Suez Petroleum Co. (GUPCO), a joint venture of EGPA and Amoco. Production was from three major fields—El Morgan, July, and Ramadan. At yearend, GUPCO began production from three small fields discovered in the Gulf of Suez over the past 2 years. Combined initial output of the three fields was 32,000 barrels per day, expected to rise gradually to 150,000 barrels per day by 1980.

Cie. Orientale des Pétroles d'Egypte (COPE), a collaboration of EGPA and ENI, produced approximately 67,000 barrels per day of oil at its two groups of oilfields on the Sinai Peninsula. Improvements in facilities were being implemented to raise production to 100,000 barrels per day. In 1977, ENI converted its joint venture with EGPA to a production-sharing agreement by which it would recover its costs in crude oil allotments.

Seven small fields in the Eastern Desert, which produced 29,000 barrels of oil per day in 1977, were operated by General Petroleum Co. (GPC), owned totally by the Egyptian Government. Other small oil-producing companies were WEPCO, FAPCO, and Nile Petroleum Co. (NIPCO).

Exploration.—Approximately 30 foreign companies held exploration permits covering nearly 320,000 square kilometers of onshore and offshore area. It was estimated that $180 million was expended on petroleum exploration in 1977. The production-sharing arrangements provided for the companies to finance all exploration and development costs and to spend a given amount on exploration over a period of up to 12 years. In the case of a commercial discovery, a joint venture with a contractual lifespan of up to 30 years would be formed with EGPA. The foreign company would recover its expenses from an initial allocation of 40% of production; the remaining output would be shared in various proportions with EGPA.

Exploration was being conducted in the following six general areas:

1. Gulf of Suez.—The Gulf of Suez Basin covers an area of nearly 20,000 square kilometers from Suez to Hurghada. Transworld Egypt Petroleum Corp., Deminex A.G., and Egyptian Petroleum Development Co., Ltd. (EPEDECO) (Japan) all reported petroleum discoveries in 1977.

2. Red Sea.—No oil discoveries have yet been made in this 25,000-square-kilometer area extending from Hurghada to the Egyptian-Sudanese border. Companies exploring the tract were Exxon Corp., Union Oil Co. of California, and a joint venture of Phillips and Hispanoil.

3. Western Desert.—The site of the most active exploration was the Western Desert, which covers 500,000 square kilometers south of the Mediterranean coast. The largest tract, covering a total of 390,000 square kilometers, was held by a joint venture of Continental Oil Co. (Conoco), Shell Oil Co., and Marathon Oil Co.

4. Nile Delta.—The Nile Delta, an area covering 36,000 square kilometers including the offshore area, has yielded two gasfields but little oil. In 1977, Murphy Eastern Oil Co. (United Kingdom) acquired a 5,200-square-kilometer concession. Both Mobil Oil Egypt and Conoco were evaluating oil and gas finds in 1977.

5. Nile Valley.—The Nile Valley Basin comprises a 100,000-square-kilometer area bound to the west by the Kharga-Wadi El Rayan uplift and to the east by the Red Sea Hills. TRIPCO Egypt Petroleum Inc. completed reconnaissance and seismic surveys in its 5,000-square-kilometer tract.

6. North Sinai.—The northern portion of the Sinai Peninsula, south to the latitude of Suez and including the Mediterranean offshore area, encompasses a total area of 40,000 square kilometers. Egypt concluded agreements with Conoco, Gulf Oil Corp., Mobil, and a Total/Agip joint venture for exploration in this territory which was recovered from Israel after the 1973 Arab-

Digitized by Google

Israeli war. Formal conclusion of these agreements awaited a United Nations decision regarding exploration rights in the Egyptian-Israeli buffer zone.

Refining.—Egypt produced approximately 11 million tons of refined petroleum products in 1977. Plans were made to increase total refining capacity to 15.5 million tons of petroleum products per year through the expansion of existing facilities. The feasibility of building an export refinery at the SUMED pipeline terminal at Sidi Kreir was under study. The refinery would have a capacity of 150,000 barrels per day and would be onstream by 1982. In 1977, refining capacity was concentrated in three companies as follows:

Company	Location	Capacity (million metric tons per year)
Gulf of Suez Petroleum Co	Suez	1.5
	Musturud	3.5
	Tanta	1.5
Nasr Petroleum Co	Suez	1.0
	Amreya	2.2
Alexandria Petroleum Co	Alexandria	2.0

Pipelines.—The SUMED pipeline began regular service in February 1977. The $500 million SUMED system consisted of two 320-kilometer, 42-inch pipelines with a combined capacity of 1.6 million barrels per day (80 million tons per year). SUMED was operated by Arab Petroleum Pipeline Co., owned by Egypt (50%), Saudi Arabia (15%), Kuwait (15%), the United Arab Emirates (15%), and Qatar (5%). By yearend, three service contracts had been concluded, with Mobil, Exxon, and Petrofina, S.A., of Belgium-Luxembourg, to allow the pipeline to operate at 25% of capacity. Other contracts were under negotiation.

Petrochemicals.—Montedison S.p.A. (Italy) was contracted for the construction of a $400 million petrochemical complex at Amreya, near Alexandria. The proposed complex, in which EGPA would have a 75% interest, was to produce 100,000 tons of low-density polyethylene, 30,000 tons of high-density polyethylene, and 60,000 tons of polyvinyl chloride per year. Startup was scheduled for 1982.

The Mineral Industry of Finland

By Joseph B. Huvos[1]

In 1977, Finland, a modest producer of mineral commodities, remained under the influence of a stagnant economy, with 6.2% unemployment and 13% inflation. The gross national product (GNP) was about $29 billion.[2 3] Mining and quarrying contributed about $119 million or 0.4% of the total. The entire mineral industry, including processing of minerals into semifinished products, contributed about 4%. Approximate mining and quarrying employment was 6,000 and for the mineral industry as a whole, about 80,000.

In 1977, important events in Finland's mineral industry included commissioning of additional cobalt production capacity by Outokumpu Oy and startup of Oy Lohja AB's talc-processing plant, Finland's first nuclear powerplant, a new 1,000-megawatt, coal-fired powerplant, and the State Fuel Center's new peat briquet plant. Kemira Oy's apatite project was approved by the Government. Outokumpu Oy completed exploration of a copper-nickel deposit. Neste Oy decided to explore for uranium near Helsinki.

PRODUCTION

Production of mineral commodities is detailed in table 1.

Volume indices (1970=100) of production in the principal sectors of the mineral industry and the country's industry as a whole are shown in the following tabulation:

Sector	1976	1977[p]
Mining and quarrying	100	104
Nonmetallic mineral processing	121	120
Iron and steel	148	182
Nonferrous metals	105	115
Petroleum refining	138	147
Industrial chemicals	170	161
All industry	125	122

The following tabulation shows the major producers of mineral commodities:

Commodity	Major producers (ownership)	Principal facilities	Percent of domestic output
Chromite	Outokumpu Oy (Government 51% and National Pension Institute 49%).	Mine at Elijärvi-Kemi	100
Cobalt ore	do	Mines at Keretti and Vuonos	100
Copper-nickel ore	do	Mines at Keretti, Vihanti, Virtasalmi, Hitura, Kotalahti, Vuonos; smelter and refinery at Harjavalta.	95
Iron ore	Rautaruukki Oy (Government 98%).	Mines at Rautavaara, Mustavaara, Otanmäki	100
Iron and steel	do	Plant at Raahe	72
	Ovako Oy	Plants at Imatra, Turku, Lappvik, Aminnefors	23
	Outokumpu Oy	Plant at Tornio	2
Lead-zinc ore	do	Mines at Vuonos, Pyhäsalmi, Hammaslahti, Vihanti	90
	Myllykoski Oy	Mine at Luikonlahti	10
Petroleum products.	Neste Oy (Government 98%)	Refineries at Porvoo and Naantali	100
Vanadium ore	Rautaruukki Oy	Iron mines at Mustavaara and Otanmäki	100
Zinc, smelter	Outokumpu Oy	Plant at Kokkola	100

TRADE

There was no significant change in the country's trade pattern in 1977. The balance-of-trade deficit decreased to about $60 million. The principal mineral exports, going mainly to Western Europe, were iron and steel, cobalt, copper, nickel, vanadium, zinc, feldspar, and talc. Mineral commodity imports made up about one-third of the value of all imports, with fuels and power accounting for about 23% of the total. Major mineral imports from the United States were steel semimanufactures, nonferrous metal ores, and nonferrous scrap. Mineral exports to the United States included steel semimanufactures, nickel and zinc metals, and other base metals including alloys. United States-Finnish trade in 1976 is shown in table 4. Finland's mineral commodity trade in 1975 and 1976 is shown in tables 2 and 3.

COMMODITY REVIEW

METALS

Cobalt and Molybdenum.—Outokumpu Oy increased the cobalt production capacity of its Kokkola plant, located on the Gulf of Bothnia, from 1,000 tons to 1,500 tons per year at a cost of $10 million. The increase in capacity was made possible partly through an agreement between Outokumpu Oy and the Government of the German Democratic Republic for the purchase of 40,000 tons of copper smelting residues per year for 8 years, valued at $100 million. The residues contain copper, cobalt, nickel, molybdenum, gold, and silver. Molybdenum, a new product at Kokkola, is to be produced at the rate of 500 tons per year for the company's Tornio stainless steel plant. The copper, nickel, gold, and silver are to be extracted at the company's Harjavalta and Pori plants near the Gulf of Bothnia.

Copper, Lead, Nickel, Zinc.—In 1977, plans were made to reopen an old silver mine on the island of Attu in the archipelago off Pori Province in southwestern Finland, for recovering the lead and zinc found there.

Exploration for copper and nickel in Vammala, east of Tampere, was completed by Outokumpu Oy in 1977. Under study was a $17.5 million project for the production of 200,000 tons of ore per year containing 0.4%

Digitized by Google

nickel and 0.3% copper.

Two major companies constituted the industry. Outokumpu Oy continued operating nine of the country's complex sulfide ore mines and controlled mineral-processing plants including the Harjavalta and Pori smelters and the Kokkola zinc smelter, all located in eastern Finland. Myllykoski Oy operated one copper mine at Luikonlahti and sold concentrates produced by the mine to Outokumpu Oy for processing.

Iron Ore.—Iron ore imports from Sweden are to be replaced in 1980 by ore mined at Polvijärvi in the U.S.S.R. near the Finnish border. The ore is to be shipped to Finland in the form of iron pellets. Iron ore mines of Rautaruukki Oy, the sole producer, have been uneconomic, and the Kolari mine is expected to be closed down in 1978; the company's Otanmäki and Mustavaara mines are economic only because of the vanadium pentoxide byproduct.

Iron and Steel.—At yearend, Ovako Oy bought out the Swedish Stora Kopparbergs Bergslags AB's half of the Lappvik steelworks located near Hangö, on the southern coast of Finland, thus becoming the sole owner. In 1977, the plant produced 335,000 tons of wirebar; 70% of this was for export.

In 1977, Finland's steel production was in the hands of four companies that shared an extensive product division, enabling them to survive the steel slump. State-owned Rautaruukki Oy's Raahe works accounted for over 72% of the country's steel output, Ovako Oy's plants 23%, and Outokumpu Oy's plant at Tornio and the Värtsilä concern at Dalsbruk, southern Finland, about 2% and 3%, respectively.

Titanium.—In 1977, Kemira Oy processed in its plant near Pori a byproduct ilmenite concentrate from Rautaruukki Oy's Otanmäki mine, augmented by some imported ilmenite concentrate. Most of the titanium pigment product was exported.

Vanadium.—In 1977, Rautaruukki Oy was Europe's largest producer of vanadium pentoxide and exported to ferroalloy manufacturers in the Federal Republic of Germany, the United Kingdom, France, Sweden, the U.S.S.R., and Czechoslovakia. The company's Otanmäki mine in central Finland and the Mustavaara mine farther north produced vanadium pentoxide as a byproduct of iron ore mining. Initial difficulties at the Mustavaara mine, which started operating in 1976, were overcome, raising the company's capacity to 5,200 tons of vanadium pentoxide per year.[4]

NONMETALS

Apatite.—The Finnish Government approved State-controlled Kemira Oy's plans for the construction of an apatite mine and concentrator at Siilinjärvi, north of Kuopio. Work started on road and rail connections to the plant site, and production is due to start by the end of 1979. Capacity was to be 2 million tons of raw ore or 215,000 tons of apatite concentrate.[5] Proved reserves were evaluated at 500 million tons of ore with an average apatite content of 10%. The concentrate produced was to replace all apatite imports from the U.S.S.R. and 40% of all other apatite imports by 1978. About 165,000 tons of calcite and some potash were byproducts.

An apatite deposit located at Sokli in Kuopio Province was under study by Rautaruukki Oy with the help of Soviet experts for a fee of $3.5 million. In 1978, exploration was to be intensified and a $7.5 million pilot plant was to be built. Rautaruukki Oy was waiting for the Government to subsidize transportation costs and for more favorable phosphate prices on the world market before investing the $250 million needed for a project large enough to supply all Finnish phosphate needs.

Cement.—In 1977, there were four cement plants in Finland, with capacities totaling 2.7 million tons. Oy Lohja AB operated an 850,000-ton-per-year plant at Virkby near Helsinki. Paraisten Kalkki Oy operated a 190,000-ton-per-year plant at Kolari in the Lappland region and the Lappeenranta and Pargas plants on the southern coast, with capacities of 460,000 tons and 1.2 million tons, respectively.

Pyrite and Sulfuric Acid.—Pyrite concentrates from Myllykoski Oy's Luikonlahti mine, located near Kaavi, were roasted for sulfuric acid at Kemira Oy's Siilinjärvi fertilizer plant. About 150,000 tons of roasted pyrite was sold for iron production. Smelter gases at Harjavalta, Kokkola, and Siilinjärvi were converted by Kemira Oy into sulfuric acid at a rate of about 1 million tons of acid per year.

Stone.—In 1977, Finland operated 12 major limestone, dolomite, and wollastonite mines—6 by Paraisten Kalkki Oy, 3 by Oy Lohja AB, and 1 each by Ruskealan Marmori Oy, Rauma-Repola Oy, and Oy K. Forström AB.

Talc.—Production of micronized talc started at Oy Lohja AB's new $10 million micronized talc facility at Vuonos near

Outokumpu. The capacity of the plant was to be expanded to 230,000 tons per year in 1978. Feed came from Polvijärvi, located at a distance of 20 kilometers, and reserves were evaluated at 40 million tons containing about 60% talc, 40% calcite, and 0.18% nickel; the nickel was separated at Vuonos and processed further by Outokumpu Oy. Some nickel-bearing talc was also mined at Lahnalampi near Sotkamo and Polvijärvi near Lohja. Both ores were concentrated at the Vuonos plant.

MINERAL FUELS

In 1977, Finland remained about 85% dependent on imported fuels, mostly crude oil and coal, with a major share of the oil and all of the natural gas supplied by the U.S.S.R. Domestic fuel production was mainly of hydroelectric power, peat, fuelwood, and industrial waste. Table 5 shows the supply and apparent consumption of fuels and power for 1976 and 1977.

Coal.—At yearend, Imatran Voima Oy (IVO), the Finnish electric utility company, commissioned a 1,000-megawatt, coal-fired powerplant at Inkoo, west of Helsinki, to be operated entirely with imported coal.

Nuclear Power.—In January, Finland's first nuclear powerplant became operational at Lovisa, 90 kilometers east of Helsinki, operated by IVO. The two 440-megawatt reactors (the first of which came onstream in 1977) were built by Atomenergoexport of the U.S.S.R. Construction continued at the country's second nuclear powerplant site at Olkiluoto on the western coast near Rauma, being built for Teollisuuden Voima Oy, which is owned predominantly by private industrial groups. Two 660-megawatt-electric units were to be supplied by Almänna Svenska Elektriska AB (ASEA)-Atom of Sweden. Fuel for the plant is to be supplied mainly by Canada and is to be enriched in the U.S.S.R. and fabricated in Sweden.

Helsingin Seudun Lampovoima Oy, jointly owned by IVO and four cities of greater Helsinki, was formed for the purpose of building a 3,000-megawatt-electric nuclear powerplant. The plant was to heat the district and generate 1,000 megawatts-electric of power.

Peat.—A 30,000-ton-per-year peat briquet plant started production for the State Fuel Center in 1977 at Peräseinäjoki in southwestern Finland; a 30,000-ton-per-year peat coke plant also operated at the same site.

Petroleum and Natural Gas.—Neste Oy, the Government-controlled oil company, operated the country's only two oil refineries, at Porvoo and Naantali in southern Finland, with capacity totaling 15 million tons per year. The refineries processed imported crude, much of it supplied by the U.S.S.R., which also supplied, by pipeline, all gas imports to the country.

Uranium.—Neste Oy, the State-owned oil-refining monopoly, planned to explore for uranium at Junninsuo near Mäntsälä, north of Helsinki. Another area of interest for uranium ores was the eastern part of Uusimaa Province.

The Mineral Industry of France

By Roman V. Sondermayer[1]

The mineral industry of France produced only moderate amounts of most crude materials domestically, but remained a significant processor of substantial quantities of certain imported crude mineral commodities during 1977. The mineral processing sector overall was of greater economic significance to France as a whole than was mining; however, the value of extracted minerals was significant to certain local areas in terms of their economic well-being and the employment provided.

The most prominent minerals and metals produced in France during 1977, with production expressed in approximate percentages of the world total, were as follows: Arsenic, 20%; diatomite, 12%; gypsum, 9.9%; fluorspar, 8%; uranium, 7%; potash, 6%; bromine, 5%; lead metal, 5%; iron ore (gross weight), 4%; pig iron, 4%; aluminum, steel, and zinc metal, each 3%; and bauxite and iron ore (iron content), each 2%.

Principal events in the mineral industry included: The action of the Government to improve the use of copper scrap; the Government's plan to save the French steel industry; the reorganization of the Government-owned fertilizer industry; and closure of a petroleum refinery.

PRODUCTION

A generally downward trend in production reflected economic problems in the country. Table 1 shows the latest figures on French mineral production. Both private companies and the Government, through State-owned corporations, produce mineral commodities at home and abroad. The Bureau de Recherches Géologiques et Minières (BRGM) was an important instrument of the Government in securing raw materials for the domestic economy by exploration and ventures abroad.

Kerosine	do.	282	866	770
Distillate fuel oil	do.	273,384	309,401	303,920
Residual fuel oil	do.	220,486	243,617	240,783
Lubricants	do.	7,582	8,909	9,364
Other:				
Liquefied petroleum gas	do.	32,180	33,809	21,702
Bitumen	do.	21,040	20,825	20,268
Unspecified	do.	26,881	50,016	44,661
Refinery fuel and losses	do.	60,627	53,793	71,445
Total	do.	809,035	902,197	892,260

[e]Estimate. [p]Preliminary. [r]Revised. NA Not available.

[1]Includes smectic clay.

[2]Consists of material for the ceramic and glass industries and reportedly contains pegmatite.

[3]Data include quantity for glass industry as well as for ceramic use.

[4]Excludes bituminous material.

TRADE

Tables 2 and 3 show details on the foreign trade of France. Mineral fuels remained the most expensive import items among the crude materials.

France had a positive minerals trade balance with the United States. Products of the iron and steel industry, radioactive materials, and petroleum products were the major U.S. imports from France. Coal, copper, aluminum, phosphates, and diamond were the principal commodities exported to France from the United States. Table 4 shows details of trade between the United States and France.

Table 2.—France: Exports of mineral commodities

(Metric tons unless otherwise specified)

Commodity	1975	1976	Principal destinations, 1976
METALS			
Aluminum:			
Bauxite	46,005	32,307	Switzerland 24,183; Poland 2,029.
Oxide and hydroxide[1]	385,024	330,127	Netherlands 127,404; Spain 51,462; Canada 42,166.
Metal including alloys:			
Scrap	22,294	30,605	Italy 12,712; West Germany 10,340; Belgium-Luxembourg 5,026.
Unwrought	163,850	149,193	Belgium-Luxembourg 34,987; Italy 34,388; West Germany 25,067.
Semimanufactures	130,798	163,923	West Germany 50,313; Italy 12,309; United Kingdom 12,198.
Antimony, including metal scrap	386	157	West Germany 19.
Arsenic (anhydride)	8,940	5,759	Switzerland 719; United States 575.
Beryllium value, thousands[2]	$118	$27	United States $25.
Bismuth metal, all forms	107	107	Italy 84.
Cadmium	226	353	Belgium-Luxembourg 211; United States 88.
Chromium:			
Chromite	368	396	NA.
Oxide and hydroxide	127	174	West Germany 45.
Metal	269	712	West Germany 224; Italy 102; Japan 101.
Cobalt	461	943	West Germany 195; United States 162; U.S.S.R. 160.
Columbium (niobium) metal, all forms value, thousands[2]	$28	$60	NA.
Copper:			
Matte	397	551	West Germany 191; Italy 158; Spain 88.
Metal including alloys:			
Scrap	55,784	100,508	West Germany 36,801; Belgium-Luxembourg 36,014; Italy 19,810.
Blister and other unrefined	2,183	4,439	Belgium-Luxembourg 4,360.
Refined	881	8,708	West Germany 3,433; Italy 3,012; Belgium-Luxembourg 1,480.
Semimanufactures	79,176	98,107	West Germany 39,780; Netherlands 9,244; Belgium-Luxembourg 9,202.
Gallium[3] value, thousands[2]	$5,055	$5,356	Switzerland $5,292.
Gold:			
Ashes and sweepings kilograms	5,863	1,901	Switzerland 1,486.
Metal:			
For domestic use thousand troy ounces	107	120	West Germany 15; Netherlands 11; Belgium-Luxembourg 10.
Temporary imports do.	3,439	2,739	Switzerland 2,278.
Iron and steel:			
Iron ore thousand tons	16,016	15,854	Belgium-Luxembourg 13,036; West Germany 2,813.
Metal:			
Scrap do.	2,810	3,421	Italy 2,798; Belgium-Luxembourg 210.
Pig iron including spiegeleisen[4] do.	221	227	Italy 115; Belgium-Luxembourg 55; West Germany 35.
Ferroalloys do.	429	484	West Germany 118; Italy 95; Belgium-Luxembourg 59.
Shot and powder do.	31	32	West Germany 16; Italy 6; Spain 2.
Steel, primary forms, including coil do.	1,414	1,348	Italy 685; United States 204; Belgium-Luxembourg 144.

Basic slag do.	198	187	Switzerland 102; Austria 44; Italy 31.
Other do.	100	44	Poland 12; Belgium-Luxembourg 6.
Potassic do.	742	578	Belgium-Luxembourg 223; Italy 94; West Germany 73.
Ammonia, anhydrous do.	259	210	West Germany 87; Spain 44.
Flint (pebbles)	89,548	85,220	West Germany 23,522; Belgium-Luxembourg 20,333; United Kingdom 11,062.
Fluorspar	109,337	92,135	West Germany 56,886.
Graphite	589	1,029	West Germany 548; Spain 120.
Gypsum and anhydrite, including plasters thousand tons	1,068	932	Belgium-Luxembourg 435; West Germany 182; Netherlands 152.
Iodine	61	9	NA.
Lime	236,133	301,065	Belgium-Luxembourg 141,818; West Germany 128,796.
Magnesite, including calcined	516	461	NA.
Mica	2,746	3,142	United Kingdom 1,292; West Germany 582; Belgium-Luxembourg 445.
Pigments, mineral, including iron oxides	2,064	2,707	Algeria 497; West Germany 326.
Pozzolans, Santorin earth, etc	2,081	1,317	NA.
Precious and semiprecious stones, except diamond[6] value, thousands[3]	$22,886	$21,196	Switzerland $11,151; United States $2,146; West Germany $1,732.
Pyrite, gross weight	75	22	NA.
Salt	106,899	128,885	West Germany 96,413; Belgium-Luxembourg 20,032.
Sodium and potassium compounds, n.e.s.:			
Caustic soda	355,474	442,111	Guinea 88,052; Brazil 70,202; Yugoslavia 57,405.
Caustic potash and sodic and potassic peroxides	6,568	6,695	United Kingdom 1,670.
Stone, sand and gravel:[7]			
Building stone:			
Crude and partly worked, n.e.s	103,160	100,598	Belgium-Luxembourg 63,986; Switzerland 12,180; West Germany 11,111.
Worked:			
Slate, including crude	39,741	80,779	Notherlands 24,411; West Germany 18,458; Belgium-Luxembourg 10,526.
Not specified	13,114	14,937	Belgium-Luxembourg 7,980; West Germany 3,425.
Dolomite, chiefly refractory grade	44,863	37,481	Ivory Coast 9,790; Belgium-Luxembourg 8,737; West Germany 6,688.
Gravel and crushed stone thousand tons	11,921	10,292	West Germany 7,572; Switzerland 1,425.
Limestone (except dimension)	174,589	152,558	West Germany 82,454; Belgium-Luxembourg 67,924.
Quartz and quartzite	8,733	2,431	United Kingdom 142.

Table 2.—France: Exports of mineral commodities —Continued

(Metric tons unless otherwise specified)

Commodity	1975	1976	Principal destinations, 1976
NONMETALS —Continued			
Stone, sand and gravel[7] —Continued			
Sand excluding metal bearing thousand tons	3,522	3,858	West Germany 2,030; Switzerland 886; Italy 685.
Sulfur, elemental do	539	742	United Kingdom 288; Netherlands 81; Italy 79.
Talc and steatite	63,397	59,426	West Germany 16,532; United Kingdom 11,131; Spain 8,126.
Other:			
Crude	263,020	266,613	Switzerland 247,791.
Slag, dross, and similar waste, not metal bearing, from iron and steel manufacture thousand tons	1,021	1,162	West Germany 601; Belgium-Luxembourg 530.
Oxides and hydroxides of magnesium, strontium, barium	7,253	9,912	U.S.S.R. 3,741; West Germany 1,716.
Fluorine	23	--	
MINERAL FUELS AND RELATED MATERIALS			
Asphalt and bitumen, natural	27,082	44,405	Belgium-Luxembourg 35,968; United Kingdom 8,193.
Carbon black	37,255	44,364	West Germany 14,926; Italy 7,273; Spain 6,822.
Coal and briquets:			
Bituminous coal	552,420	594,129	West Germany 347,180; Belgium-Luxembourg 127,649.
Briquets of bituminous coal	85,354	50,047	United Kingdom 42,379; Italy 3,828.
Lignite	14,999	19,007	All to Spain.
Coke thousand tons	719	939	West Germany 191; Belgium-Luxembourg 143.
Gas, natural million cubic feet	5,372	6,040	Belgium-Luxembourg 3,019; Switzerland 2,886.
Hydrogen, helium, rare gases	935	2,116	Belgium-Luxembourg 1,451.
Peat, including briquets	NA	1,790	NA.
Petroleum refinery products:			
Gasoline thousand 42-gallon barrels	15,785	23,613	Netherlands 6,297; Switzerland 5,277; United Kingdom 4,464.
Kerosine and jet fuel do	7,270	6,641	Switzerland 2,407; West Germany 1,196.
Distillate fuel oil do	26,841	29,228	Switzerland 12,548; West Germany 11,981.
Residual fuel oil do	21,345	20,566	Italy 7,326; West Germany 4,448; Sweden 2,039.
Lubricants do	2,771	3,220	Belgium-Luxembourg 612; United Kingdom 443; West Germany 354.
Other:			
Liquefied petroleum gas do	5,881	8,236	Spain 3,724; Portugal 1,183.
Bitumen, petroleum coke, other residues do	2,479	2,006	West Germany 994; Switzerland 630; Belgium-Luxembourg 218.
Coal-, petroleum-, or gas-derived crude chemicals	193,746	204,857	West Germany 104,079; United Kingdom 47,083.

NA Not available.
[1]Excludes artifical corundum.
[2]Based on an exchange rate of 4.80 francs = US$1.00. in 1975 and 4.7796 francs = US$1.00 in 1976.
[3]Includes indium and thallium.
[4]Includes cast iron and shot, grit, powder, and sponge of iron and steel.
[5]Includes alkali, alkaline-earth, and rare-earth metals except sodium and mercury.
[6]Includes synthetic and reconstituted stone.
[7]Excludes flint and industrial limestone.

Table 3.—France: Imports of mineral commodities

(Metric tons unless otherwise specified)

Commodity	1975	1976	Principal sources, 1976
METALS			
Aluminum:			
Bauxite	1,456,000	2,269,601	Guinea 1,716,778; Australia 382,930.
Oxide and hydroxide[1]	15,708	24,501	West Germany 14,074; Netherlands 4,067; United States 3,419.
Metal including alloys:			
Scrap	25,190	31,729	Belgium-Luxembourg 12,369; West Germany 10,093.
Unwrought	217,903	251,404	West Germany 67,132; Netherlands 53,517; Greece 30,515.
Semimanufactures	107,442	175,419	West Germany 64,341; Belgium-Luxembourg 47,411; Netherlands 21,149.
Antimony:			
Ore and concentrate	5,045	10,829	Republic of South Africa 2,825; Bolivia 2,436; Thailand 2,180.
Metal, all forms	527	563	Belgium-Luxembourg 259; Spain 130.
Arsenic, anhydride and acid	2	42	NA.
Beryllium metal, all forms value, thousands[2]	$406	$529	United States $484.
Bismuth	640	747	Bolivia 286; Belgium-Luxembourg 219.
Cadmium	694	559	Belgium-Luxembourg 170; Japan 122; Netherlands 94.
Chromium:			
Ore	354,109	345,481	Madagascar 105,832; U.S.S.R. 98,614; Republic of South Africa 68,387.
Oxide and hydroxide	2,397	5,695	West Germany 1,591; United Kingdom 1,467; Italy 1,464.
Metal, all forms	65	69	Japan 31; United Kingdom 24.
Cobalt:			
Ore	9,158	8,679	All from Morocco.
Oxide and hydroxide	170	198	Belgium-Luxembourg 183.
Metal, all forms	681	796	Zaire 377; Belgium-Luxembourg 126.
Columbium and tantalum:			
Ores[3]	1,241	196	All from Canada.
Metals, all forms:			
Columbium value, thousands[2]	$187	$155	West Germany $69.
Tantalum	23	24	West Germany 11; United States 8.
Copper:			
Ore and concentrate	879	31	NA.
Matte	872	1,179	United Kingdom 833; West Germany 202.
Metal including alloys:			
Scrap	14,228	16,762	United States 3,417; West Germany 2,849; Belgium-Luxembourg 2,152.
Blister and other unrefined	26,777	23,894	Zaire 10,835; Belgium-Luxembourg 4,807; Chile 4,518.
Refined	2,816	366,734	Belgium-Luxembourg 92,396; Chile 56,376; Zambia 47,980.
Semimanufactures	92,400	153,180	Belgium-Luxembourg 72,857; West Germany 36,027; Italy 19,303.
Germanium, gallium, etc. value, thousands[2]	$616	$1,032	Belgium-Luxembourg $661; West Germany $207.
Gold:			
Ashes and sweepings kilograms	6,213	319	Switzerland 225; Spain 66.
Metal:			
For domestic use thousand troy ounces	313	418	Netherlands 225; West Germany 129.
Temporary imports do	3,506	2,797	Switzerland 2,186; Republic of South Africa 289.
Iron and steel:			
Ore and concentrate, except roasted pyrite thousand tons	13,169	14,057	Brazil 4,206; Mauritania 2,245; Liberia 1,886.
Roasted pyrite	107,093	81,402	Italy 41,274; West Germany 24,546; Spain 15,578.
Metal:			
Scrap	278,066	280,677	Belgium-Luxembourg 139,603; West Germany 78,137; United Kingdom 44,345.
Pig iron, spiegeleisen, other[4] thousand tons	329	457	West Germany 344; Canada 24.
Ferroalloys do	204	192	New Caledonia 94; West Germany 19; Belgium-Luxembourg 16.
Steel, primary forms do	1,250	2,195	Belgium-Luxembourg 1,157; West Germany 688; Italy 133.

Table 3.—France: Imports of mineral commodities —Continued

(Metric tons unless otherwise specified)

Commodity	1975	1976	Principal sources, 1976
METALS —Continued			
Iron and steel —Continued			
Metal —Continued			
Semimanufactures:			
Bars, rods, sections[5] thousand tons	2,035	2,545	Belgium-Luxembourg 892; West Germany 857; Italy 391.
Universals, plates, sheets do	2,594	2,958	Belgium-Luxembourg 1,361; West Germany 704; Japan 142.
Hoop and strip do	266	430	Belgium-Luxembourg 220; West Germany 128; Italy 35.
Rails and accessories do	57	35	Belgium-Luxembourg 16; United Kingdom 14; West Germany 5.
Wire do	115	172	Belgium-Luxembourg 69; West Germany 55; Netherlands 16.
Tubes, pipes, fittings do	401	540	West Germany 185; Italy 133; Spain 60.
Castings and forgings, rough do	31	42	West Germany 22; Italy 5; Switzerland 5.
Lead:			
Ore and concentrate	129,803	93,452	Canada 28,532; Ireland 13,200; Morocco 12,514.
Oxide	1,475	2,085	Belgium-Luxembourg 1,111; West Germany 420; East Germany 378.
Metal including alloys:			
Scrap	12,599	6,611	Belgium-Luxembourg 3,397; Netherlands 1,307; West Germany 1,030.
Unwrought	57,798	56,388	Belgium-Luxembourg 21,752; United Kingdom 7,084.
Semimanufactures	734	631	Belgium-Luxembourg 398.
Magnesium metal including alloys:			
Scrap	271	373	Italy 216.
Unwrought	2,665	2,612	Norway 1,450.
Semimanufactures	113	193	United Kingdom 93; West Germany 42; United States 26.
Manganese:			
Ore and concentrate thousand tons	1,158	1,015	Republic of South Africa 502; Gabon 429.
Oxide	4,155	613	Belgium-Luxembourg 424; West Germany 93.
Metal, all forms	932	1,110	Republic of South Africa 604; Japan 380.
Mercury 76-pound flasks	7,774	6,411	Italy 2,495; Algeria 1,770; Spain 754.
Molybdenum:			
Ore and concentrate	7,138	7,633	Canada 4,478; United States 1,897; Netherlands 877.
Oxide	136	75	Netherlands 64.
Metal, all forms	213	168	Austria 51; United States 23.
Nickel:			
Matte	15,202	16,731	New Caledonia 15,140.
Oxide and hydroxide	212	190	Canada 146; Belgium-Luxembourg 37.
Metal including alloys:			
Scrap	1,546	1,452	Belgium-Luxembourg 311; West Germany 271; Spain 223.
Unwrought	17,030	16,043	United Kingdom 3,968; U.S.S.R. 2,922; Canada 2,470.
Semimanufactures (including anodes)	6,674	6,306	West Germany 2,036; Belgium-Luxembourg 1,319; United Kingdom 1,106.
Platinum-group metals:			
Ashes and sweepings kilograms	1,232	4,721	Switzerland 2,739; Netherlands 479.
Metals troy ounces	377,739	372,016	United Kingdom 131,271; Republic of South Africa 47,422; West Germany 37,841.
Selenium	35	36	Japan 20; Belgium-Luxembourg 5.
Silver:			
Ashes and sweepings kilograms	19,783	26,177	Switzerland 11,295; Spain 5,545; Netherlands 3,258.
Metal, all forms thousand troy ounces	35,076	47,986	United Kingdom 21,187; India 5,916.
Thorium ore (monazite)	3,961	4,414	Australia 3,985.
Tin:			
Oxide	193	222	Italy 153; West Germany 62.
Metal including alloys:			
Scrap	310	189	Italy 126; Switzerland 52.
Ingots	10,143	10,832	Malaysia 4,990; Indonesia 1,919; Belgium-Luxembourg 806.

Commodity	1975	1976	Principal sources, 1976
METALS —Continued			
Tin —Continued			
Metal including alloys —Continued			
Semimanufactures	167	119	West Germany 68; Netherlands 24.
Titanium:			
Ore	117,414	194,001	Australia 193,218.
Oxide	22,393	26,756	West Germany 11,584; Belgium-Luxembourg 5,702; Italy 3,648.
Metal, all forms	2,415	1,154	U.S.S.R. 463; United Kingdom 336; United States 170.
Tungsten:			
Ore	2,172	2,377	People's Republic of China 518; Republic of Korea 480.
Trioxide	6	65	All from West Germany.
Metal, all forms	119	186	West Germany 80; Switzerland 50.
Uranium:			
Ore	1,882	1,789	All from Nigeria.
Metal including alloys kilograms	1,557,564	1,923,731	Belgium-Luxembourg 552,234; West Germany 475,694; Spain 244,499.
Zinc:			
Ore and concentrate	389,779	463,706	Peru 105,803; Canada 102,085; Sweden 44,312.
Oxide	4,211	3,742	West Germany 951; Belgium-Luxembourg 750; U.S.S.R. 572.
Metal including alloys:			
Scrap	13,276	12,174	Belgium-Luxembourg 5,197; Italy 1,809; United Kingdom 1,403.
Blue powder	2,538	3,373	Belgium-Luxembourg 3,077.
Unwrought	74,914	34,218	United States 12,135; West Germany 8,538; Portugal 3,064.
Semimanufactures	2,222	27,380	West Germany 8,528; Belgium-Luxembourg 8,509; Denmark 3,078.
Zirconium:			
Ore	34,721	27,822	Australia 26,645.
Oxide[e]	581	1,345	United States 1,064; United Kingdom 222.
Metal	178	155	United States 140.
Other:			
Ores and concentrates	8,407	9,539	Guyana 7,051; Ireland 1,316.
Ash and residue containing nonferrous metals:			
Aluminum	9,838	7,076	Netherlands 3,176; Italy 1,755; West Germany 1,236.
Copper	1,660	1,823	Belgium-Luxembourg 1,548.
Lead	1,306	6,186	Italy 5,230.
Nickel	12	130	NA.
Zinc	1,116,044	20,745	West Germany 9,338; Belgium-Luxembourg 6,193.
Other	4,578	5,415	Italy 4,695.
Metals including alloys, all forms	253	133	West Germany 29.
NONMETALS			
Abrasives:			
Emery, natural corundum, etc	1,288	23,925	Turkey 18,639; Greece 3,120.
Pumice	15,067	5,473	Italy 2,686; West Germany 2,465.
Dust and powder of precious and semiprecious stones value, thousands[2]	$6,012	$9,188	United States $4,897; Republic of South Africa $2,468; United Kingdom $1,047.
Grinding and polishing wheels and stones	7,205	3,540	West Germany 628; Italy 398; Belgium-Luxembourg 387.
Asbestos	138,637	143,625	Canada 58,839; U.S.S.R. 47,169.
Barite and witherite	44,429	11,411	Morocco 5,485; West Germany 3,813; People's Republic of China 2,003.
Boron materials:			
Crude natural borates	111,273	131,893	Turkey 67,769; United States 60,182.
Oxide and acid	1,049	1,467	Italy 952; United States 483.
Bromine	673	997	Israel 791; United Kingdom 184.
Cement	31,399	76,672	Belgium-Luxembourg 38,829; Italy 26,834; West Germany 9,132.
Chalk	31,067	21,899	West Germany 15,659; Belgium-Luxembourg 6,097.
Clays and clay products:			
Crude:			
Kaolin, including calcined	278,500	288,500	United Kingdom 224,887; United States 32,427.
Bentonite	102,423	93,080	Italy 43,656; Greece 18,688; West Germany 15,837.
Clay and construction materials (bricks, etc.)	725,817	986,708	Italy 405,627; West Germany 327,808.
Cryolite and chiolite, natural	1,246	959	Denmark 838.

Table 3.—France: Imports of mineral commodities —Continued

(Metric tons unless otherwise specified)

Commodity	1975	1976	Principal sources, 1976
NONMETALS —Continued			
Diamond:			
Industrial, except dust value, thousands[3]	$7,785	$6,520	Ireland $2,487; United Kingdom $874.
Gem, unset ——do——	$94,564	$113,218	Belgium-Luxembourg $42,805; Israel $22,461.
Diatomite	7,688	6,861	United States 3,283; West Germany 2,116; Spain 846.
Feldspar	8,669	10,806	West Germany 7,693; Spain 2,274.
Fertilizer materials:			
Crude:			
Nitrogenous (natural sodium nitrate)	9,199	3,852	Chile 3,782.
Phosphate rock thousand tons	3,452	4,070	Morocco 1,228; Togo 867; Senegal 531.
Manufactured:			
Nitrogenous ——do——	648	1,029	Belgium-Luxembourg 325; Netherlands 275; Romania 128.
Potassic ——do——	404	323	Belgium-Luxembourg 130; Congo 93; U.S.S.R. 38.
Phosphatic:			
Basic slag ——do——	508	319	Mainly from Belgium-Luxembourg.
Other ——do——	248	536	United States 139; Tunisia 113; Belgium-Luxembourg 93.
Ammonia	295,696	228,378	Belgium-Luxembourg 118,986; Netherlands 90,838.
Flint (pebbles)	884,161	1,190,058	United Kingdom 1,181,918.
Fluorspar	16,089	2,152	West Germany 1,218.
Graphite	6,564	5,890	Madagascar 1,531; People's Republic of China 1,005.
Gypsum and plasters	14,081	18,754	Spain 8,715; West Germany 6,708.
Iodine, crude	510	590	Japan 414; Chile 151.
Lime	152,143	149,414	Belgium-Luxembourg 76,461; West Germany 71,572.
Lithium and strontium minerals	r1,454	6,407	Republic of South Africa 1,071.
Magnesite, including calcined	74,591	72,633	Greece 18,827; Austria 10,734; Japan 8,950; Spain 8,289.
Mica	9,250	4,238	India 3,139.
Pigments:			
Earth pigments, including iron oxides	613	609	West Germany 161.
Earth, other (pozzolana, Santorin earth, etc.)	NA	679	All from Netherlands.
Precious and semiprecious stones, except diamond[7] value, thousands[3]	$52,292	$47,155	Switzerland $15,099; India $10,663.
Pyrite	52,374	30,991	Norway 23,932; Spain 3,986.
Salt	131,414	127,494	Belgium-Luxembourg 66,203; Netherlands 30,556.
Sodium and potassium compounds, n.e.s.:			
Caustic soda	78,815	99,075	Belgium-Luxembourg 33,085; West Germany 28,986; Netherlands 16,779.
Caustic potash and sodic and potassic peroxides	400	487	West Germany 329.
Stone, sand and gravel:[8]			
Dimension stone:			
Crude and partly worked:			
Slate	4,502	6,327	United Kingdom 4,396; Spain 1,014.
Other	192,072	209,946	Republic of South Africa 62,806; Italy 60,777; Norway 29,222.
Worked:			
Slate	71,804	105,762	Spain 102,315.
Other	114,484	144,653	Italy 94,210; West Germany 38,699.
Dolomite, chiefly refractory grade	331,530	360,362	Belgium-Luxembourg 268,903; West Germany 84,595.
Gravel and crushed stone thousand tons	4,273	4,887	Belgium-Luxembourg 4,599.
Limestone	227,967	253,689	Belgium-Luxembourg 226,925; United Kingdom 26,764.
Quartz and quartzite	19,646	13,940	Italy 7,970; West Germany 1,822.

Table 3.—France: Imports of mineral commodities —Continued

(Metric tons unless otherwise specified)

Commodity	1975	1976	Principal sources, 1976
MINERAL FUELS AND RELATED MATERIALS			
Asphalt and bitumen, natural	2,615	3,589	United States 810.
Carbon black	63,688	75,131	Netherlands 39,372; West Germany 18,020.
Coal and briquets:			
Bituminous coal thousand tons	17,282	18,752	Poland 5,735; West Germany 4,548; United States 3,131.
Briquets of bituminous coal do	59	46	West Germany 38.
Lignite and lignite briquets do	194	174	Mainly from West Germany.
Coke do	2,885	2,712	West Germany 2,278; Netherlands 333.
Gas, natural million cubic feet	366,599	535,731	Netherlands 411,668; Algeria 124,021.
Hydrogen and rare gases	18,841	21,251	West Germany 9,791; Belgium-Luxembourg 8,236; Netherlands 2,611.
Peat, including briquets thousand tons	81	97	West Germany 52; Netherlands 23; U.S.S.R. 18.
Petroleum:			
Crude thousand 42-gallon barrels	749,035	891,601	Saudi Arabia 316,139; Iraq 122,422; Iran 107,673.
Refinery products:			
Gasoline do	15,190	16,898	West Germany 4,684; Italy 3,976; Netherlands 1,538.
Kerosine do	961	621	Italy 209; Trinidad and Tobago 144; United Kingdom 100.
Distillate fuel oil do	14,472	21,612	West Germany 3,905; Romania 2,322; United Kingdom 1,982.
Residual fuel oil do	20,546	21,425	Netherlands 4,966; Belgium-Luxembourg 3,920; U.S.S.R. 3,067.
Lubricants do	500	762	United Kingdom 175; Italy 159; Netherlands 97.
Other:			
Liquefied petroleum gas do	2,777	3,101	U.S.S.R. 1,241; Algeria 410; United Kingdom 179.
Vaseline, waxes, petroleum coke, bitumen, mixtures of bitumen, etc do	3,873	4,039	United States 2,938; West Germany 438.
Mineral tar and coal-, petroleum-, or gas-derived crude chemicals	517,133	393,713	United States 215,715; Netherlands 46,518; Belgium-Luxembourg 43,570.

[r]Revised. NA Not available.
[1]Excludes artifical corundum.
[2]Based on an exchange rate of 4.80 francs=US$1.00 in 1975 and 4.7796 francs=US$1.00 in 1976.
[3]Includes vanadium ore.
[4]Includes cast iron and iron and steel sponge, powder, etc.
[5]Includes wire rod.
[6]Includes germanium oxides.
[7]Including synthetic and reconstituted stone.
[8]Excludes flint and industrial limestone.

COMMODITY REVIEW

METALS

Aluminum.—French bauxite production declined in relation to the output in 1976, because reserves of certain deposits were exhausted. Six companies, Aluminium Péchiney, Société Anonyme de Bauxite et Alumines de Provence (SABP), Alusuisse, Etablissement Rondani, La Société Pyrénéene des Matieres Premieres Industrielles, and Etablissement Saboulard, produced bauxite. By far the largest was Aluminium Péchiney, whose output accounted for 70% of the total. Péchiney continued underground exploration of the Bauxite deposit, Bouches-du-Rhône; and Alusuisse explored in Var and Hérault. Bauxite mines were located in southern France in the Departments of Var, Hérault, Bouches-du-Rhône, and Ariége as shown in the following tabulation, with 1977 production given as a percent of the total:

Department	Percent of total
Var	75.2
Hérault	14.7
Bouches-du-Rhône	9.8
Ariége	.3
Total	100.0

The following three alumina plants, owned and operated by Péchiney-Ugine-Kuhlmann (PUK), operated during 1977:

	Production, percent of total	Approximate capacity (thousand tons per year)
Bouches-du-Rhône:		
Gardane	60	745
La Barnasse	27	350
Gard:		
Salindres	13	240
Total	100	1,335

About one-third of French alumina was exported, of which 40% was to the Netherlands, where Péchiney has an aluminum smelter. During 1977, French alumina plants operated at about 90% of installed annual capacity.

Ten smelters, all owned by PUK, were in operation in 1977, as follows:

Region and location of aluminum smelter	Production (thousand tons)		Capacity Dec. 31, 1977 (thousand tons)[1]
	1976	1977	
Pyrénées-Atlantiques:			
Noguères	102	107	115
Hautes-Pyrénées:			
Lannemezan	52	53	57
Ariége:			
Auzat	32	33	31

During 1977, PUK introduced new electrolytic cells that are more efficient, eliminate emissions of fluor, and improve working conditions without needing more area. Output per square meter of cell reportedly will be increased by 30%. The smelter at Saint-Jean-de-Maurienne was scheduled to be the first to install the new cells, which would increase annual capacity there to 92,000 tons, and later to 120,000 tons.

France was a net importer of aluminum metal. Imports contributed 39% of French supply and were essential to meet the country's aluminum demand. Domestic output accounted for about 75% of the aluminum consumption of France. Countries of the European Economic Community (EEC) supplied 52% of aluminum imports.

Antimony.—During 1977, BRGM continued exploration for antimony at Quimper (Finistère) and Lucette (Mayenne) and in Haute-Loire Department.

The French company, Société Nouvelle des Mines de la Lucette, operated a smelter and plant for production of oxides, sulfides, and other chemicals of antimony at Le Genest (Mayenne). Production was based on concentrates from Morocco.

Copper.—France remained dependent on imports of copper. Mine output was for all purposes nonexistent. Imported blister or anodes and domestic and imported scrap were used in domestic copper refineries. Only one, the 45,000-ton-per-year electrolytic plant located at Palais, Haute-Vienne, was of economic significance. The others were small units with annual production ranging between 27 and 550 tons of copper.

In 1977, consumption of primary copper was about 326,000 tons. To alleviate the economic burden of copper imports, the French Government, through a committee on plans for copper, started to encourage increased collection and expanded facilities for processing copper scrap. Major projects were to increase by 15,000 tons per year the quantity of scrap suitable for producing material similar to primary copper, to assist construction of four units for mechanical treatment of cable to recover 18,000 tons of copper per year, and systematic studies to find substitutes for copper.

Cobalt.—French production of cobalt metal increased slightly over that of 1976. Cobalt was produced from Moroccan ore in an installation situated at Pomblière-Saint-Marcel (Savoie) and owned by Métaux Spéciaux S.A.

Iron Ore.—Iron ore, with an approximate average iron content of 30%, was produced from three major basins, East (Est), West (Ouest), both in the north of France, and the Pyrenees Basin. The East basin, located in Lorraine, was the largest, accounting for about 96% of iron ore output. Because of the economic depression and lower steel production, activities at the mines were limited to production of smaller quantities of iron ore than in the past but with no major projects for expansion. In addition, strikes and decreases in iron ore reserves were among contributing causes to the lower output than in 1976. At yearend, stocks at the mines totaled 7.8 million tons of iron ore, the same as 1976. Domestic iron ore supplied 71% of the total domestic demand. Imports of high-grade iron ore leveled off; they were used both to supply coastal steel plants and to blend with low-grade domestic ores. Principal suppliers of iron ore imports (more than 1.5 million tons each) were Mauritania, Australia, Liberia, and Sweden. During 1977, exports of iron ore, largely to the nearby Belgium-Luxembourg steel industry, declined 23% when compared with 1976. The decline in exports resulted from strong competition of phosphorus ore imported from Sweden and sold in Belgium, the traditional buyer of French iron ore.

Iron and Steel.—The French steel industry came to the brink of disaster in 1977. Production was low, prices dropped, and industry debt ballooned as high operating losses continued. Action of the French Government and the EEC during the year prevented the industry from collapsing financially, and at yearend aid plans took hold, and some hope for the industry remained.

In addition to EEC plans to stabilize the steel industries of its members, the French Government established an aid plan for the industry. The "Plan Acier" (Steel Plan) included: A special labor agreement between the producers' association and the labor unions to facilitate a reduction of the workforce by 16,000 employees through mid-1979. The reduction was to be carried out mostly through early retirement and transfers, but was to be accompanied by rationalization and modernization of the structures, both physical and financial, of the industry; it was expected to be signed shortly by at least one of the other major reformist unions.

The physical rationalization includes re-

Digitized by Google

ductions in overall capacity through 1980, followed by reduced growth rates and a reorientation of production toward more finished products. This facet of the plan had already entailed the closing of several of the most obsolete facilities, most of which were located in the Lorraine region. During 1977, the financial rationalization led to the reorganization of two of the major holding companies, Marine-Wendel and Chiers-Chatillon, and to loans from the "Fonds de Développement Economique et Social" (FDES) amounting to 1.3 billion francs. An interministerial task force was organized to supervise the use of the funds. An additional 500-million-franc loan was made by the FDES during the first quarter of 1978.[2]

Geographically, the rationalization measures undertaken resulted in a shift in production toward the regions equipped with more modern facilities and with easier access to maritime shipping for both raw materials and finished products. The principal loser in this shift was the Lorraine region which has historically been steel country in France. Production in this area fell more than 10%. The Southeast, due to the increase in production at the modern (1974) facility of Société Lorraine et Méridionale a Laminage Continu (SOLMER), near Marseille, increased its production by 38%. The North, another historically important producing region, experienced a 9% decrease in production.[3]

Output of the French steel industry by geographical region is shown in the following tabulation, in thousand tons:

Region	Steel	
	1976	1977
East (Est)	10,932	9,814
North (Nord)	7,932	7,185
Center (Centre)	896	784
Southwest (Sud-Ouest)	138	127
Southeast (Sud-Est)	2,517	3,483
West (Ouest)	800	701

The growth of oxygen steelmaking in France since 1960, at the expense of the Thomas and Martin processes, is shown in the following tabulation, as a percent of total steel output:

Process	1960	1970	1976	1977
Oxygen	0.6	29.0	68.3	73.5
Electric	8.6	11.0	14.2	14.5
Thomas	60.5	41.1	11.8	8.9
Martin	29.7	18.6	5.7	3.1
Other	.6	.3	--	--

In 1977, the principal steel producers, their production in million tons, and major plants were as follows:

Sacilor-Aciéries et Laminoirs de Lorraine S.A. (SACILOR) (6.0), with plants at Boussange near Grandrange, Usine de l'Orne-Amont near Homécourt, and Rombas and Hagondange, Moselle Department.

Société Lorraine de Laminage Continu (SOLLAC) (2.0), with plants at Hayange, Knutange, Sermange, Ébange, and Florange, all in Moselle.

Société Lorraine et Mériodionale a Laminage Continu (SOLMER) (1.6), at Fos-sur-Mer near Marseille.

CREUSOT-LOIRE, Entreprise S.A. (1.3), with plants at Le Creusot, St. Etienne Leffrincroucke near Dunkerque, Imphy, and Firkny (Loire).

Lead.—France remained dependent on imports of lead concentrates to meet its smelter demand; in 1977 this dependence was close to 75%. Morocco, Ireland, and the United States were the principal suppliers.

BRGM's exploration activities resulted in confirmation of a lead-zinc deposit at Guerdèriene (Côtes-du-Nord) and of another deposit of lead-zinc and silver at Crozes (Aveyron); these were offered to the industry for further development.

Complex ore deposits of lead, zinc with silver, and copper in Brittany, discovered in the past, were of principal interest to BRGM. Results of activities were mixed during 1977. At Bodennec (Finistère), complexity of the deposit and complexity of concentration indicated that production would be uneconomic at prevailing prices for lead. At a deposit explored jointly by BRGM and Societé Nationale Elf Aquitaine (SNEA), located at Porte-aux-Moines (Côtes-du-Nord), richer ores without metallurgical problems raised hopes that one flotation plant for Moines and Bodennec ores could make economics of the Bodennec ores more attractive.

Increased production of domestic mines resulted chiefly from higher output by the Farges mine (Corrèze). The following tabulation shows the mine output for recent years in tons of lead concentrate:

	1976	1977
Largentière (Ardèche) (Peñarroya)	32,600	31,750
Malines (Gard) (Peñarroya)	3,000	3,025
Farges (Corrèze) (Société Minière de Corrèze)	3,200	6,600

Digitized by Google

The Imperial smelter at Noyelles-Godault (Pas de Calais, annual capacity 130,000 tons), owned by Peñarroya, remained the only primary lead smelter in operation in the country. In addition, Peñarroya operated secondary smelters at Saint-Denis, Villefranche-sur-Saône, and Escaudoeuvres. Aggregate production from secondary plants, including lead content of antimonial lead, was about 57,000 tons in 1977.

Imported lead supplied 21% of domestic demand. Largest suppliers of lead and lead alloys were Belgium (39%) and the Federal Republic of Germany (26%).

Nickel.—Based on imported nickel matte from New Caledonia, Société le Nickel (SLN) remained the sole nickel producer in France in 1977. SLN continued construction of a new nickel plant at Sandouville, near Le Havre, to replace the existing one, which could no longer meet market specifications. The new electrolytic nickel plant will have a capacity of 15,000 tons per year of high-purity nickel. Startup was scheduled for mid-1978. French consumption of nickel was about 18,300 tons, including metal in oxides.

Tungsten.—During 1977, France was the principal tungsten producer among the EEC countries. Two mines were in operation; the larger producer, the Salau mine (Ariège) operated by Société Minière d'Anglade and the smaller producer, the Enguialès mine (Aveyron), operated by Société Minière et Chimique du Chatelet.

BRGM and SNEA conducted exploration for tungsten in the Central Massif but had made no announcement of major discoveries at yearend.

Zinc.—Higher production of zinc resulted from increased output of high-grade ores from the Saint-Salvy (Tarn) mine, which started production in 1975. The following tabulation shows preduction at French zinc mines, in tons of zinc concentrate:

	1976	1977
Saint-Salvy (Tarn)	43,700	52,000
Les Malines (Gard)	19,210	20,580
Largentière (Ardèche)	8,460	10,100
Total	71,370	82,680

Peñarroya was the only mine zinc producer in France, supplying approximately 15% of zinc concentrate consumption. Canada, Peru, Sweden, and Ireland were the major foreign suppliers.

At the electrolytic plant at Vivier (Aveyron), owned by Vieille Montagne, construction of a plant for treatment of residues from electrolysis was completed. Trials were conducted during the second half of the year, and regular production should start in 1978. Capacity was not made public.

Three companies smelted zinc in France: Vieille Montagne operated the Vivier plant and a plant at Creil; Compagnie Royale Asturiennes des Mines produced electrolytic zinc at Auby; and Peñarroya operated its Imperial smelter plant at Noyelles-Godault.

Domestic production of smelter zinc in France during 1977 was 92% of primary metal consumption. Countries of the EEC were major suppliers of zinc to France and purchasers of French zinc.

NONMETALS

Andalusite.—Andalusite was produced from the Glomel deposit in Brittany. Denain-Anzin Minéraux S.A. produced about 30,000 tons of andalusite concentrates containing 59% Al_2O_3 and about 1% Fe_2O_3. Andalusite schist, containing about 15% of andalusite crystals that are several centimeters long, are encountered under very shallow overburden. The opencast mine is worked in 15-meter benches. The ore is blasted, crushed, and ground to a maximum size of 1.6 millimeters; it is upgraded by electromagnetic separation and a double circuit heavy-media unit. Proven reserves were reported at 4 million tons of ore. The final product is used by the European refractory industry.

Barite.—During 1977, the management of Barytine de Chaillac (Indre Department) undertook measures to increase recovery of barite. Crushing plants were modernized, new flotation circuits were added, and new buildings for storage were constructed.

La Société Industrielle du Centre operated a mine at the Rossignol deposit. There was a delay in exploration because some difficulties were encountered in acquiring land titles.

France remained a net exporter of barite, with the Federal Republic of Germany and the Netherlands continuing as the largest purchasers.

Cement.—Approximately 82% of cement capacity was controlled by 4 companies, the 2 largest of which were Société des Ciments Français S.A. with 22 plants and Ciments Lafarge France with 18 plants. France had a total installed capacity of 40.4 million tons of cement per year; during 1977, the cement industry operated at 70% of capacity.

Fertilizer Materials.—The French Government started to implement its plan for restructuring the French fertilizer industry into two new groupings, one each in the public and private sectors. In the public sector, the two Government-owned com-

Digitized by Google

panies, CdF-Chemie and Entreprise Miniére et Chimique, were to merge their fertilizer interests. In the private sector, the finalization of regrouping was not announced at yearend.

Phosphate.—France had no significant production of phosphate rock during 1977. A small output of about 19,000 tons of phosphatic chalk, with an average P_2O_5 content of 10%, from deposits in the Département de la Somme was the only natural source of phosphate in the country. However, slag from iron and steel plants continued to supply phosphorus, accounting for 15% to 20% of the total. The rest of the country's demand was met through imports from Morocco, Senegal, Togo, Tunisia, and others.

Potash.—Restructuring of the potash industry and experiments for production of potash by solution mining continued during 1977. However, in both fields results were modest.

The Government-owned Mines de Potasse d'Alsace (MDPA), part of the Government-owned Entreprise Miniére et Chimique, remained the only producer of potash in France from mines located in Alsace near Muhlhouse. Domestic output was more than adequate to meet the demand, and France was a net exporter of potash.

Fluorspar.—Demestic output of fluorspar was more than adequate to meet demand, and France was a net exporter. However, production and consumption declined, mostly because of the slowdown in the steel industry. A decrease in production at Langeac (Haute-Loire) was attributed to the mining of lower grade ores.

The largest producers of fluorspar were as follows: Sogerem/Secme (Péchiney-Ugine-Kuhlmann), which produced acid-grade fluorspar at Montroc (Tarn), Fontsante (Var), and Langeac (Haute-Loire) and metallurgical-grade fluorspar at Alban (Tarn), with a total acidspar capacity about 120,000 to 130,000 tons per year and a metspar capacity around 25,000 tons per year; Denain-Anzin Minéraux (Denain Nord-Est Longwy), with mining operations at Prades (Pyrénées Orientales) which supplies the 75,000-ton-per-year acidspar plant at nearby Olette and the 50,000-ton-per-year metspar pelletizing plant at Ria; Comifluor (owned by Péchiney-Ugine-Kuhlmann and Denain-Anzin Minéraux), which operates the flotation plant at Olette; Mines de Garrot (now a Talcs de Luzenac associate), which produces around 8,000 tons per year of metspar in conjunction with barite operations at Les Arcs (Var), although actual mines are at Pic Martin and Vallon de Largentière; and Cie. Française des Minerais d'Uranium (CFMU), which produces up to 60,000 tons per year of metspar, plus a smaller output of fines, from operations near Autun (Saône-et-Loire).

France was a net exporter of fluorspar, and the largest purchasers remained the Federal Republic of Germany, Italy, and Sweden.

Talc.—Talc was produced by Talcs de Luzenac at its mine and plant near Luzenac sur Ariège. No major events were reported. France was a net exporter of talc; the Federal Republic of Germany, the United Kingdom, and the United States were the major purchasers.

MINERAL FUELS

France was almost totally dependent on imports for crude oil and was partly dependent on imported solid fuels and natural gas. Coal was the major fuel produced in the country. The fuel position of France is shown in table 5.

Table 5.—France: Supply and apparent consumption of fuels and power

(Million tons of standard coal equivalent[1])

	Total primary energy	Coal and coke	Petroleum and refinery products	Natural gas	Fuelwood	Hydroelectric power	Nuclear power
1975:							
Production	48.0	26.7	2.6	9.7	(2)	7.3	1.7
Imports	214.6	21.3	178.3	15.0	(2)	(2 3)	(2 3)
Exports	19.6	1.7	17.9	--	(2)	--	--
Apparent consumption	243.0	46.3	163.0	24.7	(2)	7.3	1.7
1976:							
Production	50.2	26.5	2.8	9.3	(2)	9.5	2.1

Coal.—Coal production and consumption in France continued to decline although energy use increased. The sluggish performance of the iron and steel industry and consequent consumption of coke affected the demand for coal.

After several years of negotiations, the operating entity of the largely nationalized French coal industry, Charbonnages de France (CdF), concluded an agreement with the French authorities concerning subsidies to CdF by the French Government. According to the terms of the contract, the French Government will cover all expenses of CdF not related to production, such as costs of retraining miners and losses related to prices set by the French Government below market prices.

The French coal industry was concentrated in three areas: Nord-Pas-de-Calais (northern France), Lorraine (northeastern France), and Centre-Midi (central and southern France). Mines in the Centre-Midi basin were grouped in seven subbasins: Aquitaine, Auvergne, Blanzy, Cévannes, Dauphiné, Loire, and Provence. All mines in these areas were operated by CdF. Only one non-nationalized company, Houillères de Cruéjouls, was in operation in 1977, with mines in the Arjuzanx subbasin, south of Bordeaux, which delivered lignite to a powerplant at d'Alibi.

Production figures for various coal basins, by type of coal, are shown in the following tabulation in thousand tons:

	1975	1976	1977
Anthracite and bituminous:			
Nord-Pas-de-Calais	7,715	7,318	6,641
Lorraine	10,021	9,970	10,033
Centre-Midi:

Grand total	25,610	25,067	24,374

Source: Annales des Mines, Paris. No. 9-10, September-October 1978, p. 101, Sec. 11.

Mining conditions in French coal mines were difficult. Most of the mines were deep, gassy, and with thin, almost vertical, seams. However, only 1.7% of all mines were unmechanized, and those few mines with thick, horizontal seams were highly mechanized.

Salient statistics of the coal industry are shown in table 6.

Table 6.—France: Salient statistics of the coal industry

(Thousand metric tons unless otherwise specified)

	1975	1976	1977
Production, bituminous and lignite	25,610	25,067	24,374

Stocks at yearend, all mines	6,162	4,887	5,409

rRevised.

About 90% of French coal must be washed. Of the coal washed in 1977, about 57% was processed in installations with dense media; installations with piston jigs and flotation plants processed 33% and 10% of the run-of-mine coal, respectively. Capacity of all coal washeries was about 14,600 tons per hour of run-of-mine coal at yearend 1977.

France imported about 50% of its solid fuels during 1977. Imports of coal increased, but imports of coke declined. Imports from countries outside the EEC increased to 65% of total imports. Coal deliveries from the Republic of South Africa and Australia, newcomers on the French market, almost doubled when compared with coal imports of 1976.

Coke.—Reconstruction continued on the large coking complex at Carling in Lorraine. Battery No. 1 was shut off, and battery No. 2 was readied for industrial

Digitized by Google

production after completion of tests. Production of coke and semicoke in the three basins at the steel coking plants, in thousand tons for 1975-77, was as follows:

Basin	1975	1976	1977
Nord-Pas-de-Calais	3,112	2,836	2,412
Lorraine	2,139	2,052	1,952

Gas coking plants and independent producers	455	453	456
Grand total[1]	r11,340	r11,110	11,072

rRevised.
[1]Data differ from those reported in table 1, owing to a difference in source.

Sources: Charbonnages de France. Rapport de Gestion 1977 (Paris). 1977, p. 76; and Annales des Mines, Paris. No. 9-10, September-October 1978, p. 119.

At yearend 1977, installed capacity in French coking plants at basins was about 17,755 tons of coke per day. During 1977, coking plants at basins operated at about 73% of installed capacity.

The outflow of coke and semicoke to various sectors of the economy, in thousand tons and percentage of total during 1975-77, was as follows:

	1975	Percent	1976	Percent	1977	Percent
Steel industry	2,638	54.3	2,873	54.5	2,255	50.1
Other industries	1,008	20.8	957	18.2	1,000	22.2
Small industries	157	3.2	132	2.5	115	2.6

Household consumption	410	8.5	429	8.1	441	9.8
Total	4,855	100.0	5,271	100.0	4,497	100.0

Source: Charbonnages de France. Rapport de Gestion (Paris). 1977, p. 74.

Natural Gas.—Construction continued on an additional 80,000 cubic meters of underground storage space for gas in the general area of Fos, a port in southern France on the Mediterranean Sea.

Domestic output accounted for about 30% of the apparent demand of the country. The Netherlands remained the principal supplier and accounted for 70% of total imports of natural gas.

Based on existing plans, natural gas should provide 16% of the energy demand in 1985. Algeria should provide the bulk of French imports by 1990.

Petroleum.—As in the past, France was almost totally dependent on imported crude oil to meet the requirements of domestic petroleum refineries.

Exploration and Production.— During 1977, efforts were made to increase domestic crude oil production, but results were not encouraging. A total of 34 wells with 86,943 meters were drilled. Of 14 exploratory wells, with 44,724 meters drilled, only 1 was a producer. Esso S.A.F.'s well, Vulaines 1 in the Paris basin, discovered oil in the Jurassic Dogger between 1,889 and 1,910 meters. During production the test well flowed at a rate of 6.6 cubic meters per day from the fractured oolitic limestone. The well was completed and acidized through a perforated 7-inch liner. The 20 preduction wells, totaling 42,219 meters, were mostly drilled in fields in Aquitaine.

Domestic production of crude oil and condensates was only about 1% of the total refinery throughput of France. In addition to domestic production, French interests controlled production of about 75.1 million tons per year, or about one-third of French consumption, in various ventures abroad. Approximately 55% of total investment in foreign oil consisted of participations in North Sea ventures.

Refining.—During 1977, French petroleum refineries, with a total installed capacity of 171 million tons of crude, processed 118 million tons or 69% of capacity. Countries of the Persian Gulf accounted for about 76% of total refinery throughput. Countries of the Mediterranean basin followed with 9%. Nigeria supplied about half of the remaining deliveries. An older 2-million-ton-per-year petroleum refinery at Ambes

Digitized by Google

(Gironde), owned by Elf France, was closed as obsolete. Table 7 shows ownership, location, and capacities of petroleum refineries in France.

[1]Closed during 1977.

Transportation.—During 1977, the French tanker fleet comprised 82 tanker ships with a total deadweight capacity of 16.2 million tons. The average deadweight capacity was 200,000 tons. Four new tankers, with a deadweight capacity of 1.0 million tons, were commissioned during the year; one of them was the largest tanker in the world, the 555,000-deadweight-ton tanker *Pierre Guillaumat*. Five tankers, with a total tonnage of 0.4 million deadweight tons were decommissioned. Tankers under the French flag moved 81% of the crude oil delivered to France.

Several crude oil pipelines with a total length 3,700 kilometers were in service and moved about 71 million tons of crude oil during 1977. In addition, about 20 million tons of petroleum products were moved through two pipelines with a length of about 1,768 kilometers.

Uranium.—The French Government and the private sector remained active in uranium mining and processing at home and abroad. A Government-owned company, Compagnie Général des Matières Nucléaires (COGEMA), was the largest operator. In France, COGEMA explored around the mining districts of Limousin, Vendée, and Forez. In addition, exploration continued in central France in Rouergue, Lauragais/Castrais, Berry, and Bourbonnais/Morvan. Private companies, MINATOM in particular, explored in the Central Massif, Brittany, and Aquitaine.

COGEMA continued exploration and research to concentrate ores, and made an economic evaluation of the Lodève, Hérault deposit, which produces a carbonate ore that is difficult to treat. At yearend, technical problems appeared solved, but exploitation still appeared uneconomic.

Compagnie Minière Dong-Trieu continued preparations for startup of an opencast mine and concentrator at its concession at Mailhac-sur-Benaize. Production was

Digitized by Google

scheduled for 1979.

Uranium in France was produced by COGEMA, Société Central de l'Uranium et des Minerais et Métaux Radioactifs (SCMURA), Compagnie Française de Minerais d'Uranium (CFMU), Société Industrielle et Minière d'Uranium (SIMURA), and Société des Mines d'Uranium du Centre (SMUC), a subsidiary of CFMU, COGEMA, and Société des Asphaltes du Centre.

The following tabulation shows mine production of uranium in metric tons:

Company	Location of mine	Ore	Uranium content
COGEMA	Limousin	521,000	842
Do	Vendée	312,000	503
Do	Forez	137,000	512
CFMU	Lozère	136,000	136
Do	Creuse	16,500	56
SIMURA	Morbihan	8,600	36
SMUC	Corrèze	8,000	51
SCUMURA	Cantal/Creuse	58,000	100
Total		1,197,100	2,236

Source: Annales des Mines, Paris. September-October 1978, p. 34.

This tabulation includes low-grade ores (0.02%) produced by COGEMA at Limousin and Vendée and by CFMU at Lozère.

A sixth yellowcake plant started production in 1977. Three plants, Bessines, l'Escarpiere, and Bois Noir, were operated by the Société Industrielle de l'Ouest (SIMO); one by CFMU at Lozère; one by COGEMA at Guingnon; and the new one by SCMURA at Sain Pierre-du-Cantal.

At Lozère, expansion of the concentrator was completed with the addition of one beneficiation unit to the existing plant. The Lozère plant has a capacity of 200 tons of uranium per year.

The Mineral Industry of Gabon

By Candice Stevens[1]

Gabon's mineral sector contributed approximately 65% of the 1977 gross national product (GNP) estimated at $3 billion,[2] with revenues derived chiefly from petroleum, uranium, and manganese production. Despite having one of the highest per capita incomes in Africa, Gabon's economy suffered from problems engendered by inflation, a small labor force, and a large external debt. Inflation was estimated at 20% to 25% in 1977, and expatriate labor was being used in development projects. In 1977, Gabon received standby credit of $18 million from the International Monetary Fund to help curb the inflation rate and improve the public debt situation.

In the third 5-year plan (1976-80), the Government mounted an ambitious program to develop the country's natural resources and create a diversified industrial base. Expenditures were dependent upon levels of petroleum production. The basic plan, which projected investments totaling $3.5 billion, was founded on a decrease in oil production to 8.3 million tons per year by 1980; an alternative plan, which would involve investments of nearly $4 billion, assumed that production would be maintained at the annual rate of 11 million tons through 1980 by exploitation of new petroleum discoveries. The Government was also enforcing the Provision pour Investissements Diversifiés (PID), which required that petroleum companies invest up to 10% of their profits in industrial ventures in Gabon. The choice of investment must receive the approval of the Government, which then acquires a 51% interest in the venture. In the mineral sector, projects being financed through PID funds included the Cie. Gabonaise—ELF de Raffinage (COGER) refinery, the Soc. des Ciments de Gabon cement plant at Ntoum, the nitrogen fertilizer plant at Port Gentil, and the Soc. Nationale de Transportation Maritime (SONATRAM) tanker fleet.

Work continued throughout the year on the Trans-Gabon Railroad, which is to link the manganese mines at Moanda, the uranium mines at Mounana, and the iron ore deposits at Belinga to a deepwater port under construction at Santa Clara, 15 kilometers north of Libreville. The total length of 950 kilometers comprised a 340-kilometer link from Owendo to Booué; a 360-kilometer link between Booué, Moanda, and Franceville; and a 250-kilometer section connecting Booué and Belinga. The 13-company European consortium constructing the railroad planned to inaugurate the first link between Owendo and Ndjolé in early 1978. Annual capacity of the railroad is to be 2.2 million tons of timber, 2 million tons of manganese, 10 million tons of iron, 60,000 tons of hydrocarbons, and 500,000 tons of miscellaneous goods, in addition to passengers.

PRODUCTION AND TRADE

Production of Gabon's major mineral commodities—manganese, uranium, and crude petroleum—decreased from the 1976 levels. Manganese production is scheduled to increase from the current rate of around 2 million tons per year to approximately 4

Digitized by Google

million tons per year upon completion of the Trans-Gabon Railroad. Uranium production is to undergo a 50% increase in capacity upon commissioning of the underground mine at Oklo. Production of petroleum is expected to remain at the 11-million-ton-per-year level, assuming that new fields supplement a decline in output from older deposits. New cement plants and a new petroleum refinery are to augment the production of these commodities. Gabon also produced small amounts of gold and nonmetals.

Mineral exports accounted for approximately 91% of the total export value in 1977. However, a reduction in the current balance-of-trade surplus was projected, owing to declining petroleum exports. Petroleum, which provided 81% of the export earnings, was sold primarily to the United States, France, and other African countries. Manganese was the second largest earner (8% of the total export value) and was exported to the United States and Canada (40%), France (22%), Japan (10%), and other Western European countries. Virtually all uranium production was exported to France.

Transport congestion at the two main trading centers of Owendo and Port Gentil was to be eased by expansion of Gabon's port facilities. Construction began in April 1977 on extensions to Port Gentil, including the addition of two 600-meter docks. A new $100 million mineral port was also under construction at Santa Clara. The port complex, being built by Soros Associates (United States), is to include a breakwater-protected harbor where general cargo, metallurgical coke, and miscellaneous metallurgical products can be handled. Two belt conveyors were being designed to carry 8,000 tons of iron ore and 4,000 tons of manganese per hour. Manganese, uranium, and iron ore are to be transported to Santa Clara by the Trans-Gabon Railroad for direct shipment.

COMMODITY REVIEW

METALS

Gold.—Gold sales by Soc. Gabonaise de Recherches et d'Exploitations Minières (SOGAREM) have been declining in recent years and fell to about 2,600 troy ounces in 1977. Gold was produced by independent workers in the areas of Etéké, Lastoursville, Makokou, and Ndjolé. SOGAREM, in conjunction with Bureau des Recherches Géologiques et Minières (BRGM), continued its investigation for deposits to supplement the older workings.

Iron.—The completion of the Trans-Gabon Railroad is to enable exploitation of the Mekambo group of iron ore deposits on the Ivindo River at Belinga. Iron ore mining is to be undertaken by Soc. des Mines de Fer de Mekambo (SOMIFER), a multinational consortium of steel companies, in partnership with the Gabonese Government. In 1977, a study was in progress to determine the reserves and average phosphorus content of the Mekambo deposits, where re-

Digitized by Google

serves were previously estimated at 566 million tons averaging 65% iron. Exploitation of the deposits was tentatively scheduled for 1982 at an average annual rate of 10 million tons of ore. Output is to be transported by the Trans-Gabon Railroad to the new ore-handling port of Santa Clara, which is to be capable of accommodating carriers of 250,000 deadweight tons. Exploration for iron ore was also being conducted in the Tchibanga region in southwestern Gabon.

Manganese.—Gabon, the world's third largest producer of manganese, produced nearly 1.8 million tons of metallurgical-grade ore and 78,000 tons of battery- and chemical-grade ore in 1977. Reserves at Moanda, situated 50 kilometers west of Franceville, were estimated at 210 million tons of salable product grading 48% manganese. Open pit mining since 1962 has been under the direction of Cie. Minière de l'Ogooué (COMILOG), owned by United States Steel Corp. 44.1%, BRGM 19.8%, Cie. de Mokta 17.1%, the Gabonese Government 10%, and Soc. Auxiliaire du Manganese de Franceville 9%. Production is expected to reach 4 million tons of manganese annually upon completion of the Trans-Gabon Railroad. Ore has been transported by a 76-kilometer, overhead chain conveyer from Moanda to Mbinda on the Congolese border, then along a 286-kilometer stretch of the Chemin de Fer Congo-Ocean railroad for export from the port of Pointe-Noire. COMILOG continued its investigation of manganese deposits on the Okouma Plateau north of Moanda; the Gabonese Government planned to take a 10% to 25% interest in any venture to exploit the deposits.

The major share of the high-grade ore produced by COMILOG was used to produce batteries by Soc. Gabonaise des Piles (SOGAPIL). The SOGAPIL plant, which had a production capacity of 6 million 1.5-volt batteries per year, was owned 20% each by the Gabonese Government, Wonder Industries Corp., and COMILOG, with the remaining shares divided among private banks and individuals. Output was sold for domestic use and exported to the Congo and Zaire.

Soc. Gabonaise des Ferroalliages (SOGAFERRO) continued its study of construction of a ferroalloys plant at Franceville. Production of 85,000 tons of ferromanganese and 50,000 tons of silicomanganese was scheduled to begin in 1981, pending completion of the Grand Poubara Dam. Principal shareholders in SOGAFERRO were Okura Trading Co., Ltd. (Japan) 25%, COMILOG 15%, the Gabonese Government 10%, Union Carbide Corp. (United States) 10%, Acièries de Paris et d'Outreau (France) 10%, Elkem-Spigerverket A/S (Norway) 10%, Applications de la Chimie de l'Electricité et des Métaux S.A. (SADACEM) (Belgium) 10%, and Tassara (Italy) 10%. The production of the $75 million plant is to be exported to the United States, Europe, and Japan.

Uranium.—The production capacity of Cie. des Mines d'Uranium de Franceville (COMUF) is to increase from 1,000 tons of U_3O_8 in 1977 to 1,500 tons in 1980. Preparations were underway for underground mining at the Oklo uranium deposits, currently being mined by opencast methods, to begin in 1978. Feasibility studies were also being conducted on exploitation of the Boyindzi and Okelobondo deposits. Total reserves at the three deposits, all located in the Mounana area 25 kilometers north of Moanda, were estimated at 20,000 tons of uranium metal. Ownership in COMUF was divided among Cie. de Mokta (28.13%), the Gabonese Government (25%), France's Commissariat à l'Énergie Atomique (CEA) (15%), Minatome S.A. (13.12%), Cie. Française des Minerais d'Uranium (7.5%), Cie. de Gestion d'Investissements Internationaux (COGEI) (7.5%), and Cie. des Mines de Huaron (3.75%). CEA continued uranium exploration in its two concession areas near Franceville and Cocobeach.

Uranium ore was processed at the Mounana plant, which had a capacity of 240,000 tons of ore annually and produced preconcentrates containing 35% to 55% uranium metal. Final processing was at the Gueugnon plant in Saône-et-Loire, France. A plant to produce yellow cake with a content of 70% to 75% uranium metal was scheduled for completion at Mounana in 1978. Annual capacity of the plant, which was expected to cost $40 million, was to be 1,000 tons of uranium metal.

NONMETALS

Cement.—Gabon's only clinker-grinding plant, owned by Soc. des Ciments d'Owendo S.A., produced approximately 160,000 tons of cement in 1977. Principal shareholders in the Owendo plant were the Gabonese Government 20% and Ciments Lafarge S.A. (France) 71.3%. Production capacity of the plant was increased to 270,000 tons per year in 1976 by the installation of an additional grinding unit. To reduce dependence on imported cement, two other facilities were under construction. Soc. des Ciments de

Digitized by Google

Gabon was created in 1976 to build a clinker-grinding plant with an annual capacity of 100,000 tons at Franceville. A second plant at Ntoum was to produce 350,000 tons of clinker annually from local limestone deposits, where reserves were estimated at 20 million to 30 million tons. Construction of the two facilities was to be by Creusot-Loire Entreprise (France). Shareholders in Ciments de Gabon were the Gabonese Government 51%, Elf Gabon 19%, Ciments Lafarge 15%, and Ciments d'Owendo 15%. Cement production for both domestic use and export was to commence in 1979.

Fertilizer Materials.—Construction continued during 1977 on the nitrogen fertilizer plant at Port Gentil by Soc. Gabonaise de Chimiques. Using natural gas feedstock associated with Gabon's petroleum production, the plant is to have an annual capacity of 60,000 tons of ammonia. Shares in the company were owned by N'Ren Corp. (United States) 35%, Elf Gabon 31.85%, and the Gabonese Government 33.15%. Startup was scheduled for 1978, with the greater share of production to be exported to other African countries.

Marble.—In its first year of operation, the new marble cutting and polishing plant at Tchwanga, near Doussé-Ossou, produced 7,000 square meters of marble. The plant was operated by Soc. Italo-Gabonaise des Marbres (SIGAMA), which was owned by the Gabonese Government 25% and a consortium of Italian firms 75%. Reserves of marble in the area were estimated at 2 million tons. The major share of output was exported to Western Europe.

MINERAL FUELS

Petroleum.—Gabon, Africa's fifth largest producer of petroleum and a member of the Organization of Petroleum Exporting Countries (OPEC), produced approximately 11.2 million tons of oil in 1977. Production was expected to continue at this level for the next few years but was then expected to decline if no new substantial discoveries were made. Although Gabon has a few large oilfields, most of the fields are of moderate size, and approximately 80% of the production originates from ocean deposits. Recoverable oil reserves were estimated at 80 million tons in 1977.

Gabon produced three different types of crude oil: Mandji oil of 30° API gravity in the area of Port Gentil; Gamba oil of 31.7° API gravity in the area near Sette Cama; and Lucina oil of 30.9° API gravity farther south near Mayumba. In 1977, the price of Mandji crude was raised 8.4% from $13.20 to $14.31 per barrel, and the price of Gamba crude was raised 9.7% from $13.50 to $14.81 per barrel.

The largest producer in Gabon was Elf Gabon, owned 75% by Essence et Lubrificants de France—Entreprise de Recherches et d'Activités Pétrolières (Elf-Erap) and 25% by the Gabonese Government. With 13 offshore and 5 onshore fields in production, Elf Gabon had an output of more than 170,000 barrels per day, accounting for about three-fourths of Gabon's production in 1977. The largest producing field was Grondin, which accounted for about one-fourth of total Gabonese production from 20 wells. The Grondin field, situated 80 kilometers south of Port Gentil, was being used as a test site for deepwater production technology. A subsea station operated by electronic remote control, thereby avoiding the need for floating platforms, was installed in 1976. Equipped with production equipment and three production wellheads, the subsea station was placed 60 meters deep, but the equipment and techniques were to be functional at a 600-meter depth. Production from the first well drilled began in December 1976; during 1977, two additional wells were drilled.

Elf Gabon held several joint production ventures with other oil companies. Shell Gabon, owned 25% by the Gabonese Government and 75% by Royal Dutch/Shell, started oil production jointly with Elf Gabon at the Gamba field in 1963 and the Ivinga field in 1968. Elf Gabon, in conjunction with Mitsubishi Oil Co., Ltd., operated the smaller Merou and Baliste fields. Elf Gabon, in partnership with the U.S. firms Ocean Drilling & Exploration Co. and Ocean Oil and Gas Co., also brought the offshore Breme field into production in 1976.

Petroleum exploration continued both onshore and offshore under concessions granted to about 20 international companies and covering approximately 155,000 square kilometers of territory. The terms of the prospecting licenses required producing companies to reinvest up to 10% of their profits in domestic industrial enterprises, Government participation of 25% in case of commercial discovery, refining of 50% of crude output in local facilities, and training of local personnel. In 1977, a total of 40 exploratory and development wells were

Digitized by Google

drilled: 31 were completed for oil, 1 was completed for gas, 5 were dry, and 3 were suspended.

The refinery operated by Soc. Gabonaise de Raffinage (SOGARA) produced 1.6 million tons of refined petroleum products in 1977. The refinery, located at Port Gentil, was supplied by crude from the deposits at Ile Mandji by way of an 18-kilometer pipeline. SOGARA was owned 30% by the Gabonese Government, 18.75% by Elf Gabon, 18.75% by Cie. Française des Pétroles, and the remainder by a group of petroleum-marketing companies. Gabon's second refinery, also at Port Gentil, operated by COGER, came into production in 1977 but did not reach full capacity of 1.5 million tons per year. COGER was owned 30% by the Gabonese Government and 70% by Elf Gabon. About 40% of Gabon's production of petroleum products went to Soc. Nationale de Distribution Pétrolière (PIZO), the Gabonese national oil-distribution company. The remainder was sold to Gabon's partners in the Central African Economic and Customs Union, which included Cameroon, the Central African Empire, Chad, and the Congo.

The Mineral Industry of the German Democratic Republic

By George Rabchevsky[1]

The industrial development of the German Democratic Republic (G.D.R.) is essentially determined by the fact that the country has limited indigenous raw material resources. The G.D.R., therefore, has to rely on its material processing industry and foreign trade. The only marketable raw materials it has are lignite, potash, salt, and feedstock for the cement, glass, and ceramics industries. On a smaller scale, the G.D.R. also mines ores of several nonferrous metals, such as copper and tin, and extracts small quantities of natural gas.[2] In 1977, the G.D.R. remained a world leading producer of lignite and potash. Furthermore, the G.D.R. claims to have the largest chalk deposits in Europe, concentrated on the Baltic Sea Island of Rugen.

Due to its lack of domestic raw materials, the G.D.R. in 1977 had difficulties in coping with the inflation of prices for imported raw materials. For example, 1977 was the third year in succession in which the G.D.R. showed a deficit in its trade balance with the U.S.S.R. and other countries, despite its tremendous export efforts.

The 1977 national income of the G.D.R. increased 5.2% over the previous year's national income, to 155 billion Marks (M).[3] This growth, however, did not meet the Government's goal of a 5.5% increase. Overall, the 1977 economic plan was not met, and tasks planned for 1978 were reduced. Slower growth than was anticipated for national income was mainly due to shortfalls in the 1976 and 1977 harvests. Of all the member countries of the Council for Mutual Economic Assistance (CMEA),[4] the G.D.R. has the highest per capita income. Manufacturing is the G.D.R.'s most important sector, accounting for about 60% of national income, and employing at least 40% of the working population. Industrial production rose 5.4% over 1976 production levels to M94.5 billion, an increase of M13,800 million, compared with the planned target of 5.1%. Despite considerable bottlenecks in the supply of intermediate products and spare parts, production in the manufacturing industry increased in 1977. This increase resulted primarily from steady productivity increases of 6% in 1976 and 5.2% in 1977.[5] The 1977 growth rate (at 1975 prices) for the energy and mining sector was only 4.3% (compared with 6% in 1976); for the processing industry, the growth rate was 5% (compared with 5.6% in 1976); and for the construction industry, the rate of growth was 4.7% (compared with 5.4% in 1976).[6]

The 1977 State budget of the G.D.R. amounted to M122.2 billion, reflecting a growth rate of 4%. An 8% growth rate is planned for 1978. In 1977, M2 billion was spent on research. Capital investments in industry during 1977 increased 9% over 1976 investments, compared with a 7.9% increase in investments from 1975 to 1976. More than half of the G.D.R.'s industrial investment was in heavy industry, especially in the coal and energy, ore mining, metallurgy, and chemical industries.[7] Approximately 60% of the total industrial investments anticipated under the current 5-year plan are earmarked for the raw materials industries. For example, expenditures for research and exploration of minerals are planned to be nearly twice the amount spent for these efforts under the last 5-year plan.[8]

The current 5-year plan (1976-80) calls for total increases of 28% in national income, 34% in industrial production, and 30% in productivity over the 5-year period. Al-

Digitized by Google

though during the past 2 years some sectors have fallen short of planned targets, the economic outlook for 1978 is more favorable. The national income in 1978 is expected to rise 5.2% and increases are also forecast for industrial production (5.7%) and in foreign trade turnover (11%). Total expenditures for science and technology in 1978 are planned to amount to over M7 billion, 14% more than was spent in 1976. The 1978 State budget set both revenues and expenditures at M130,617.5 million.[9]

The 1978 draft plan stipulates production of 254.5 million tons of brown coal, 7.7 million tons of rolled steel, 96.8 billion kilowatt-hours of electricity, and the processing of nearly 20 million tons of crude oil and 11.7 billion cubic meters of natural gas. As in 1977, plans are to funnel 60% of 1978 investments into the production of raw materials, such as coal and potash mining, metallurgy, geologic exploration, and the chemical industry. The production of electricity in 1978 is planned to rise 5.2% over 1977 production to 96,750 million kilowatt-hours. Under the 1978 plan, the output of existing surface lignite mines is to increase by 6 million tons over 1977 output. Moreover, 35 million tons of raw brown coal is expected to be mined from surface mines that have been newly developed under the current 5-year plan.

Production of metallurgical products and rolled steel is planned to increase 4% from 1977 to 1978. Production in the chemical industry, which contributes 15% to overall industrial production, is planned to increase 6.7% during this period. Also during this period, industrial production in the glass and ceramics industries is planned to rise 6.9%.[10] Output forecasts under the 1978 economic plan are shown for the following products: City gas, 5,962 million cubic meters; oil processing, 19,950 thousand tons; finished rolled steel products, 4,519 thousand tons; other metallurgical products, 2,760 thousand tons; steel pipe, 448 thousand tons; cement, 12,500 thousand tons; potash fertilizer, 3,330 thousand tons (K_2O equivalent); and nitrogen fertilizer, 907,000 tons (nitrogen content).[11]

The 1978 plan also stresses production quality and conservation. For example, electrical energy consumption in 1978 is planned to be reduced 3%, compared with 1977 consumption; and savings in rolled steel for the same period are projected at 4.8% in the machine building industry and 3.7% in the construction industry. Consumption of cement is expected to fall 1.9% during the period.[12] The overall consumption of energy, raw materials, and other materials in industry is expected to be reduced 4% for 1978, compared with 1977 consumption.

PRODUCTION

Since most mineral statistics for the G.D.R. were not published, much of the production data in table 1 were estimated and represent at best an order of magnitude.

The metallurgical industry is one of the largest and most important sectors of the G.D.R. economy. Production of metallurgical products was valued at M13.2 billion in 1976; this was approximately 7.9% of the Nation's total industrial output. The metallurgical industry has overwhelmingly concentrated on production of ferrous metals; however, aluminum, tin, copper, zinc, lead, titanium, gallium, and selenium are also produced. With domestic iron ore deposits nearing depletion and production of nonferrous ores declining, the G.D.R. has a very weak mineral base for its metallurgical industry and can expand production only through increased imports of raw materials and scrap recycling. In carrying out its current 5-year plan, the G.D.R. is concentrating on production of higher quality steel, while relying on imports to meet domestic requirements for lower grades of steel.

The current 5-year plan envisions progressive enlargement of the metallurgical industry in order to support expansion of the G.D.R.'s important mechanical engineering industry. The plan emphasizes the use of indigenous sources and recycling to meet demand for metallurgical products. Under the plan, crude steel output is to be increased by 30% to 34%, and output of rolled steel is to be increased 39%. For nonferrous metals, the 5-year plan establishes a goal of expanding production of aluminum and tin while maintaining copper production at current levels. Plans are for investment to be concentrated in automation and modernization of existing plants, rather than in new capital construction.

The centers of the G.D.R. metallurgical industry are Eisenhuettenstadt, Brandenburg and Hennigsdorf, Riesa, Groeditz, Nordhausen, Karl-Marx-Stadt, Unterwell-

Digitized by Google

enborn, Freiberg, Freital, and Aue. Of the 10 major metallurgical centers, all produce iron, steel, and associated products; and 4 also specialize in titanium, aluminum, gallium, nickel, selenium, tin, and zinc products.

According to Government reports, more than 160,000 workers are employed in the mining and metallurgical industry. In 1977, these workers fulfilled the prescribed annual production plan, including plans for the production of potash and lignite. Furthermore, production exceeded target levels by 30,000 tons for pig iron and by 20,000 tons for rolled steel. Industrial production of coal and energy in 1977 increased 4.8% over the previous year's production.[13] The G.D.R.'s economy in 1977 produced on a daily basis 700,000 tons of raw lignite, 21,000 tons of rolled steel, 31,000 tons of cement, 52,000 tons of petroleum, and 32 million cubic meters of natural gas.[14]

In 1977, the Ministry of Mining, Metallurgy, and Potash exceeded its production quotas by 6.4%, increasing production by 3.4% over the 1976 quota.[15] According to the head of the Ministry, workers conserved 170,000 tons of rolled steel annually in industry and construction, reduced annual consumption of rolled steel in metallurgy by 4.6%, and reduced consumption of nonferrous metals by 2.6%.[16]

Scrap and secondary raw materials are assuming a steadily growing significance in the G.D.R.'s raw materials base. Almost 75% of the G.D.R.'s crude steel and 70% of its copper are produced from secondary raw materials.[17] During the current 5-year plan, for example, the collection and utilization of ferrous and nonferrous metal scrap increased by 15%. Steel scrap is the most important raw materials base. In the production of steel and nonferrous metals in 1977, the G.D.R. utilized as much as 100% of the corresponding raw materials processing volume for each of these industries. In addition, the G.D.R.'s Minister of Geology stressed the use of ground slag from the Mansfeld complex as an additive in cement production, as well as the use of granitic and rhyolitic rocks as feldspar raw materials bases for the glass and ceramic industries, and the use of special gravels for the production of flint glass. Over 100 million tons of mineral raw materials is reportedly lost each year in mining, processing, and transportation, out of a total annual output of approximately 460 million tons.[18]

In 1977, the G.D.R.'s metallurgical industry employed about 130,000 workers, 22% of whom are women. The metallurgical industry comprises 7% of the Nation's total industrial production. Reportedly, workers in this sector produce a total output of over M15 billion per year.[19]

Table 1.—German Democratic Republic: Production of mineral commodities

TRADE

Detailed data on trade with individual countries or groups of countries are not reported in official G.D.R. statistics. The official 1977 trade book simply lists imports as follows: The socialist countries contributed 70%, the developing countries contributed 5%, and the "capitalist industrial countries" contributed 25%. Trade with the developing countries rose 15% over 1976 trade levels, totaling M4.5 billion. This trade was mainly with countries such as Algeria, Angola, Ethiopia, India, and Iran. Trade with developed market economy countries, however, declined 10% and totaled M21 billion. Countries in this category included Denmark, Finland, Sweden, the Federal Republic of Germany (F.R.G.), Holland, Austria, Japan, and the United States. Trade with the United States totaled M829 million.[20] Trade with the centrally planned economy countries in 1977 increased 14% over the previous year and totaled M65.5 billion. Trade with the Soviet Union increased 17% and totaled M32.5 billion. Trade between the G.D.R. and the F.R.G. rose only 3% over the previous year—to M8.7 billion—after expanding at an average annual rate of 8.4% from 1970 to 1976.[21]

Potash continued to be one of the G.D.R.'s major export commodities in 1977, and was purchased by India and Brazil, as well as by the centrally planned economy countries. Brown-coal briquettes and rock salt were two other main mineral export commodities.

Most of the G.D.R.'s imports come from the centrally planned economy countries, primarily from the Soviet Union, which supplies 36% of the G.D.R.'s imports. Crude oil and natural gas are imported mostly from the Soviet Union, but also from Syria, Iraq, and Egypt. The planned extension of the Friendship (Druzhba) natural gas pipeline from Orenburg, U.S.S.R., into the G.D.R. is expected to result in further gas imports. The import of hard coal from the Soviet Union declined in 1977. Since 1950, the G.D.R. has received from the Soviet Union more than 170 million tons of petroleum, more than 55 million tons of iron ore, and 47 million tons of rolled steel. Bituminous coal and sulfur are imported from Poland; bituminous coal, coke, and rolled steel are shipped from Czechoslovakia, and bauxite and clay are imported from Hungary. Aluminum and titanium oxide are imported from Yugoslavia, and imports of copper and zinc from that country are planned to begin in 1979. Nickel is expected to be imported from Cuba during the next 5-year plan.[22]

In 1977, total imports of M49.8 billion were 9% higher than in 1976, but total exports rose only 6% to M41.8 billion. Despite a considerable effort, the G.D.R. did not succeed in preventing an increased trade deficit in 1977.[23] The 1977 foreign trade turnover increased 7% to M91.6 billion. Plans for 1978 envisage an 11% increase in the trade turnover. Foreign trade, however, will probably continue to place a strain on the economy because prices of raw materials are expected to rise further. The 1978 import-export pattern is expected to be the same as in 1977. 1978 exports are planned to consist of machines and equipment (51%); fuels, mineral raw materials, and metals (11%); semifinished products (10%); and chemical products, fertilizers, and building materials (14%). Imports are also expected to consist of machines and equipment (32%); fuels, mineral raw materials, and metals (30%); semifinished products (25%); and chemical products, fertilizers, and building materials (10%).[24] The country's main import commodities in 1978 are projected to be about 18 million tons of oil, 2 million tons of iron ore, 700,000 tons of asbestos, and more than 25,000 tons of titanium oxide.

According to the 5-year plan (1976-80) agreement, the G.D.R. is to import from the Soviet Union over the 5-year period 88.2 million tons of crude oil, 216 billion cubic meters of natural gas, 21 million tons of bituminous coal, 15.9 million tons of rolled steel, and 212,000 tons of copper. In 1978, the G.D.R. expects to receive from the Soviet Union 17.7 million tons of crude oil, 3.7 billion cubic meters of natural gas, 2.95 million tons of rolled steel, 1.36 million tons of iron ore, as well as large quantities of nonferrous metals, asbestos, and other raw materials.[25]

[5]Total excludes 96,000 troy ounces of unknown value imported from Poland.

[6]Total import of nitrogenous fertilizer is expressed in N content.

COMMODITY REVIEW

METALS

Aluminum.—Estimated domestic production of primary aluminum in 1977 totaled 65,000 tons. Large quantities of the country's 1977 aluminum consumption were imported from the U.S.S.R. The G.D.R.'s estimated consumption of aluminum rose from 210,000 tons in 1976 to 215,000 tons in 1977.[28]

Imports of aluminum from Western countries fell drastically in 1977 to 1,600 tons, compared with 44,200 tons in 1976. The G.D.R.'s remaining aluminum imports came from the U.S.S.R. The G.D.R. in 1977 imported 396 tons of aluminum alloys. Its exports of aluminum to Western countries, however, increased 51% in 1977 to 20,400 tons. 1977 exports to the F.R.G. increased 64% over 1976 exports to 19,867 tons. Exports of unwrought aluminum to the United Kingdom declined in 1977 to only 70 tons, compared with 607 tons in 1976, but imports from the United Kingdom rose to 339 tons, compared with only 30 tons in 1976. Exports of aluminum and aluminum alloys to the Netherlands in 1977 totaled 24 metric tons, and imports also totaled 24 tons. Imports of aluminum from Norway totaled 1,005 tons. Japan in 1977 imported 396 tons of aluminum alloys from the G.D.R.

Primary aluminum is produced at two plants, the Electrochemisches Kombinat at Bitterfeld (55,000 tons annual capacity) and the Electrochemisches Kombinat (Lauta Werke) at Lauta (30,000 tons annual capacity). The G.D.R.'s only alumina plant (70,000 tons annual capacity) is also located at Lauta. The G.D.R. does not have any indigenous bauxite deposits and imports all of its bauxite from Hungary and Yugoslavia.

The introduction in 1976 of continuous cast rolling of aluminum at the Nachterstedt Light Metal Works resulted in increased work productivity in 1977 and a rise in product quality. This innovation was introduced with aid from the Soviet Union. An energy saving of 300 kilowatt-hour per ton was reported as a result of the renovation.[27]

Cadmium.—The estimated production of cadmium remained the same in 1977 as in 1976, at 18 metric tons, but 1977 consumption dropped 10 tons to 450 tons. All of the G.D.R.'s requirements for cadmium are met by imports from the U.S.S.R. Cadmium is obtained as a smelting byproduct at the

Digitized by Google

VEB Mansfeld Kombinat Wilhelm Pieck plant at Eisleben and the Electro works at Weida, Thuringia.

Copper.—Production of refined copper was estimated at 51,000 tons in 1977, but has virtually come to a standstill since 1975. The estimated consumption of refined copper dropped from 118,000 tons in 1976 to 115,000 tons in 1977. The only producing copper mines during the year were near Sangerhausen. Deposits at Mansfeld-Eisleben-Hettstedt are almost depleted and the mines have been closed since 1974.

In 1977, the G.D.R. exported 8,123 metric tons of unwrought copper to the F.R.G; this reflected a slight decline in copper exports to that country since 1976. Imports of unwrought copper and semimanufactures from the F.R.G., however, increased 145% to 30,762 metric tons. Most of the G.D.R.'s imported copper in 1977, as in previous years, came from the Soviet Union. Other 1977 imports came from Chile (1,400 tons of electrolytic copper) and Peru (10,516 tons of refined copper). Copper exports from the G.D.R. went to Belgium-Luxembourg (2,634 tons of refined copper) and Italy (996 tons of copper, alloys, and semimanufactures), in addition to the F.R.G.

Construction of a copper drawing and rolling mill at the copper and silver works in Hettstedt, a part of the Mansfeld combine, was completed in 1977. The new mill occupies a space of 4,000 square meters. Most of the equipment and technical labor used to build the mill was supplied by the Soviet Union. Full production is expected to start late in 1979.

Iron and Steel.—The G.D.R.'s iron mining industry is old, and now most of its iron ore resources are nearly depleted and production figures are no longer reported. The production of steel and pig iron is also inadequate to meet domestic demand and therefore the G.D.R. depends heavily on imports to meet its requirements for these commodities. The Soviet Union is practically the sole supplier of pig iron and rolled steel to the G.D.R. Nevertheless, the G.D.R. exported 1,654,000 tons of semifinished and finished steel in 1977.

Iron ore deposits of the G.D.R. are of four types: (1) the hydrothermal-metasomatic siderite and limonite ores of the post-Variscan (Kimmeridgian) age related to the marginal faults of the Thuringian Forest area, (2) the volcanic-sedimentary deposits of the Devonian age in the Thuringian and the Harz Mountains, (3) the marine-sedimentary iron ores of the Ordovician age in Thuringia and of the Jurassic and Cretaceous ages in the area north of the Harz Mountains, and (4) the Skarn iron ores of contact-metamorphic origin related to Variscan granite in the Erzgebirge. Of these types, only the Devonian volcanic-sedimentary deposits and the Ordovician and Jurassic marine-sedimentary deposits have had economic importance.

About 75% of the G.D.R.'s steel production is made from scrap. The production of crude steel is targeted at 7.5 million tons for 1980. Production of special corrosion-resistant steels began in the G.D.R. about 10 years ago and has now reached 60,800 to 70,000 tons annual output. The production of superhard welding and stainless steels increased more than 20% from 1976 to 1977. Production of stainless steel is anticipated to rise 50% by 1980, compared to production for 1970.

The methods of crude steel production in the G.D.R. remained the same in 1977 as in the previous year. Most of the steel, or 69%, was produced by the open-hearth method; 21% was produced in electric furnaces; oxygen was used to produce 9%; and other methods were used for the remaining 1% of production. In 1977, the G.D.R. expanded its production of semifinished steel, primarily through the utilization of electric furnaces in combination with continuous casting.[28]

The recent reconstruction of the Wilhelm Florin steel and rolling mill of the Henningsdorf complex contributed to a production increase of 39% in 1977, compared with production for 1976. In 1977, the Henningsdorf steel and rolling mills complex, which is the main producer of reinforcing rods, modernized its Konti-Five steel plant. In 1977, it produced about 180,000 tons of rolled steel and plans to produce 400,000 tons in 1978. The completed second stage of the continuous thin-sheet rolling mill at Henningsdorf also contributed to increased 1977 production of all rolled steel products.

In 1977, the entire Maxhütte steel mill at Unterwellenborn was renovated, thus increasing production of block steel by 58%. The Siemens-Martin furnace at the Brandenburg steel and rolling mill began operating in 1977, raising steel production by 2,000 tons more than 1976 production. The mill continued to be the largest producer of crude steel in the G.D.R.[29]

Digitized by Google

Reportedly, the G.D.R. negotiated a contract at the 1977 spring fair in Leipzig with the Italian firm Danieli & Co. for construction of a steelworks at Brandenburg with two electric arc furnaces and continuous casting. Capacity is expected to be 550,000 tons per year and the plant is expected to be completed by 1980.[30] A new plant was also commissioned at Finow for the production of light steel sections.

Of the 1.5 million assorted castings manufactured annually in the G.D.R., most are being made of cast iron that has had spherical graphite added to it. In 1977, the old furnace at the Torgelow combine was being replaced by a 4-ton electric furnace for the production of high-quality castings. An experimental foundry was being constructed at Lobenstein that will be equipped with induction-type smelting furnaces. Another foundry near Uckermünde on the Oder estuary was under construction and was expected to be completed in 1978.

The Bandstahlkombinat Herman Mattern in Eisenhuettenstadt Ost is reportedly planning to increase its production of cold-rolled sheets to 14.5 million tons per year by 1980. The plant's production of galvanized products is also expected to increase from 160,000 tons in 1977 to 206,000 tons by 1980. The Bandstahlkombinat also plans to install a pickling line for coils 2 to 6 millimeters thick and up to 1.85 meters wide, increase annealing facilities, and expand slitting and cut-to-length capacities.

Lead and Zinc.—The production of lead and zinc is fluctuating and the G.D.R.'s mine output of zinc has virtually ceased due to depletion of ore. The G.D.R.'s lead and zinc deposits are found in the vicinity of Freiberg in a low-grade complex of polymetallic ores that contain lead, zinc, silver, pyrite, and fluorspar in thin beds. The ores are concentrated by flotation in two plants at Freiberg.

The 1977 estimated consumption of lead, despite indigenous ore depletion, increased 2% over 1976 consumption to 95,000 metric tons. Zinc consumption increased 5% to 68,000 tons. The production of refined lead in 1977 was estimated at 37,000 tons and zinc production was estimated at 15,500 tons.

In 1977, the G.D.R. reportedly imported 5,900 metric tons of lead from Belgium-Luxembourg, 919 tons from Austria, 250 tons from Mexico, and 500 tons from Peru. Some 1,000 tons of zinc was imported from Norway and 2,000 tons came from Australia. Most of the G.D.R.'s lead and zinc is imported from the Soviet Union. Imports of zinc from Western countries in 1977 dropped off 46% from 1976 levels, to 8,500 tons. The G.D.R. exported 980 tons of refined lead during the year to Western countries, a drop of 25% from the previous year's lead exports.

Nickel.—The G.D.R.'s nickel industry is centered at the Aue (St. Egidien) nickel plant. The estimated 1977 production of refined nickel in the G.D.R. was 2,800 tons. Consumption of nickel went up slightly, from 10,000 tons in 1976 to 10,500 tons in 1977.

Silver.—Silver is mined in the G.D.R. as a byproduct. The estimated primary silver production in 1977 was unchanged from the previous year's production, at 50 metric tons (1,600,000 troy ounces).

The G.D.R.'s annual requirement of about 500 tons of silver reportedly came from three sources: (1) ore extraction, which is in decline because of increasing mining costs and diminishing domestic deposits; (2) increased imports from Western countries resulting from decreasing deliveries from the CMEA countries (85% of the G.D.R.'s imported silver is purchased with convertible currencies on the London Metals Exchange); and (3) recovery of silver from secondary raw materials and waste, sources that accounted for 25% of the G.D.R.'s 1977 silver output. According to one report, the G.D.R. presently produces 22 tons of silver through fixing-bath reduction.[31]

Tin.—More than 50% of tin requirements are imported from market economy countries. The G.D.R.'s tin deposits are low grade and located in the Erzgebirge along the country's southeastern border. Tin ore is mined at Altenberg, Sadisdorf, and Ehrenfriedensdorf. The ore contains from 0.20% to 0.35% tin and is beneficiated by gravity concentration to a product that is approximately 40% tin. Consumption of tin in the G.D.R. remained almost the same in 1977 as it was in 1976, at 2,700 tons. In 1977, the G.D.R. imported 12,600 tons of tin plate from the Soviet Union, reflecting a decrease of 4,500 tons from the previous year's imports from that country.

According to the current 5-year-plan target, tin production is to increase 45% by 1980, and production costs are planned to go down by 12% per ton.[32] According to the Ministry of Foreign Trade, the G.D.R. pos-

Digitized by Google

sesses sufficient deposits of tin ore to increase production as planned and to meet the country's growing demand for tin.

A newly developed mine and a new tin ore processing plant were completed in 1977 at Altenberg in the Dresden area. The new unit will make it possible for the G.D.R. to expand the production of both ore and tin concentrate according to plans. The tin concentrate from Altenberg is expected to be processed at the Freiberg plant.

The new tin smelter at Freiberg also contributed significantly to an increase in tin recovery from domestic sources. In 1977, the Albert Funk mining and metallurgical complex in Freiberg (Bezirk Karl-Marx-Stadt) expanded production. Equipment for the new tin smelter, which is part of the Albert Funk complex, was provided by the Soviet Union, and Soviet experts helped assemble the smelter.[33]

NONMETALS

Barite and Fluorite.—The 1977 estimated output of barite remained the same as in 1976 at 31,000 tons. Barite is processed at the Lengenfeld fluorite and barite plant in the southern part of the country. The estimated 1977 production of fluorite was 100,000 tons, mined principally from the Harz Mountains and the Thuringian Forest region.[34] The exploration depth for fluorite is expected to go from the present depth of 600 meters to 1,000 meters in 1979.

Cement.—There were approximately 32 cement plants spread throughout the G.D.R. in 1977, with the densest concentration in the south. The largest plant is the Karsdorf cement works near Halle; its 1977 estimated annual kiln capacity of 4.1 million tons is expected to increase to 4.3 million tons in 1978. The other five major cement works are Rüdersdorf (2.8-million-ton capacity), Bernburg (2.7-million-ton capacity, including the Dessau works), Deuna (2.0-million-ton capacity), Bitterfeld (200,000-ton capacity), and Pisterlitz (200,000-ton capacity). The Halle district produces 25% of all the G.D.R.'s building materials.

The Karsdorf cement works introduced production of a new sulfate-resistant cement in 1977, with full production slated to begin in January 1978. All of the G.D.R.'s cement plants are managed by VEB Zementkombinat, with headquarters located in Donau. The 12.1-million-ton production of 1977 is expected to rise to 12.5 million tons in 1978 and to 13.0 million tons in 1979. The cement industry employed about 15,000 workers in 1977.[35]

Chalk.—The 1977 estimate of the G.D.R.'s chalk production remains the same as in 1976, at 50,000 tons. Chalk is mined on Rügen Island near Sassnitz, Europe's largest deposit of compact chalk. About 30% of the domestic chalk production is exported.

Clays.—New clay quarries are being opened and production is being upgraded. The country's richest kaolin deposits are near Bautzen, and the major kaolin works are located at Cominau, Salzmünde, Spergau, and Kemmlitz. Bentonite is imported from Hungary. Kaolin is imported from Hungary and Czechoslovakia, but the G.D.R. also exports kaolin.

The G.D.R.'s Ministry of Glass and Ceramics Industry employs approximately 20,000 workers, and 15,000 of these workers are engaged in the production of technical glass. The technical glassworks in Ilmenau was under construction in 1977. Forty mining enterprises of the glass and ceramic ministry are reportedly upgrading their output of kaolin, glass sand, glass lime, and quartzite so that plans to increase production by 25% between 1979 and 1980 can be realized. Production of these materials is currently estimated at 3 million tons annually.[36]

Fertilizer Material.—The G.D.R.'s total fertilizer production in 1976 reached 4.5 million tons of nutrients, reflecting a slight increase of 2% over the previous year's output. This production was made up of potassium (K_2O) fertilizers (72%), nitrogen fertilizers (19%), and phosphorous (P_2O_5) fertilizers (9%).

Nitrogen.—Production of nitrogen fertilizers in 1977 increased to a total of 839,000 tons (nitrogen content), reflecting an 8% increase over the previous year's production. The increased production is due mainly to the operation of three new units of the VEB Stickstoffwerk Piesteritz. The G.D.R.'s nitrogen fertilizer production is centered near Leipzig, with one important plant located at Schwedt near the Polish border. The G.D.R. imports and exports small quantities of nitrogen.

Phosphate.—The production of phosphatic fertilizers (in terms of P_2O_5 content) in the G.D.R. fluctuates and was 403,000 tons in 1977, reflecting a decrease of 5% over the previous year's production. The G.D.R. exports insignificant amounts of its phosphatic fertilizers but imports large quantities of

Digitized by Google

raw phosphate and apatite concentrates and some manufactured fertilizers. In 1977, a total of 1,491,000 tons of phosphate rock was imported, of which 1,200,000 tons of apatite concentrate came from the Soviet Union, 171,000 tons of phosphatic rock came from Morocco, and 120,000 tons of phosphatic rock came from Tunisia. Several marine phosphorite horizons of the Middle Oligocene age have been found around Leipzig. The deposits occur as sandy concretions and as fossilized organic remains.

Potassium.—In 1977, the G.D.R. remained the world's third largest producer of potash. Production rose to a record high of 3.2 million metric tons of K_2O in 1977, an amount in excess of the planned target. The 1978 planned production target is 3.34 million tons of potash. It is estimated that the G.D.R. will produce 4 million tons of potash in 1980. Present identified reserves are estimated at 300 to 900 million tons of K_2O, and total reserves are estimated at 5 to 7 billion tons.[37]

All potash enterprises are subordinate to the VEB Kombinat Kali, and the industry is divided into four groups, the Kalibetrieb Werra, the Kalibetrieb Süd Harz, the Kali und Steinzalzbetrieb Saale, and the Kalibetrieb Zielitz. Each group is responsible for the operation of its own mines. The Kalibetrieb Zielitz operates the G.D.R.'s newest mine at Wolmirstedt and is the country's largest potash producer, with an estimated annual capacity of 1.1 million tons of K_2O. The three mines at Werra near Eisenach are the country's largest potash-producing mines, with combined annual capacity estimated at 1.4 million tons. The other major potash mines are, in descending order by production, the Bischofferode mine at Erfurt (250,000 tons annual capacity), Rossleben at Halle (200,000 tons), Sondersshausen at Erfurt (150,000 tons), Bleicherode at Erfurt (150,000 tons), Sollstedt at Erfurt (120,000 tons), Menteroda at Erfurt (120,000 tons), and Teuschenthal at Halle (30,000 tons).

The Minister of Mining, Metallurgy, and Potash emphasized in 1977 that increased production of mineral fertilizer in the potash industry must be achieved not only through intensified production from existing potash plants, but also from the mining and processing of new types of crude salt. He stressed, for example, increased processing of carnallite, a type of crude salt. However, this would require the development of a completely new technology for carnallite extraction and processing, and would require strict environmental controls.[38] By 1977, more than 50,000 hectares of land that was once mined for potash had been restored to cultivation; of this restored land, 30% is used for crop farming.

Minable potash deposits in the G.D.R. are concentrated in five beds that comprise a mixture of different potash ores, such as sylvinite, carnallite, and hartsalz. Of the four regions where potash is mined, the Werra region, where the Merker center is located, is the most important. In the Werra Fulda Valley, in the southern Harz area, the Zechstein potash deposits are mined at 11 mines. Since the recent opening of the Zielitz mine, potash is also mined on the North German Plain. The two potash beds of the Werra Fulda Valley are nearly horizontal, but in places they are strongly disturbed with vertical displacements of up to 8 meters. The carnallite ore, containing from 12% to 15% K_2O, is mined 800 meters below the surface, using the room-and-pillar method that is common to all potash mining in the G.D.R. Mining is complicated, however, by the high gas content of the ore and by overlying water-saturated strata. The southern Harz mines are between 400 and 1,000 meters deep. The ore mined from these mines is mainly harzsalz averaging from 12% to 15% K_2O, but because of difficult roof conditions, only 30% to 34% of this ore is recovered. At the Zielitz mine on the North German Plain, potash is mined at a depth of 700 to 800 meters from a sylvinite bed 6 to 9 meters thick with a uniform slope of 18 to 25° and an average K_2O content of 15%.[39]

In 1977, a new plant for the production of high-grade potash fertilizer was being constructed in the Suhl area as part of the Werra potash enterprise of Merkers/Rhoen, the country's largest producer. This new factory is the second largest investment project of the G.D.R.'s potash industry and is planned to upgrade the present obsolete plant. More than 8,000 workers are employed by the Werra enterprise, and 30,000 workers are employed in the entire potash industry.

MINERAL FUELS

It was reported that the coal and energy industry of the G.D.R. fulfilled its 1977 production plan. Approximately 69% of the G.D.R.'s total energy requirements are satisfied by lignite and lignite is used to

Digitized by Google

produce 83% of the country's electrical energy. Daily consumption of lignite in the G.D.R. amounts to 690,000 tons plus 109,000 tons of lignite briquets. Sources for the generation of electrical energy in the G.D.R. in 1977 were as follows: Of the total 92 billion kilowatt-hours of electricity that was produced, 83.3% was produced from raw lignite; 0.9% from lignite briquets; 0.6% from bituminous coal; 1.4% from hydraulic power; 5% from nuclear energy; 3% from oil; and the remainder from other fuels, including natural gas. With the exception of the Greifswald nuclear powerplant, all major plants in the G.D.R. use lignite as the primary source of energy.[40]

Production in excess of national quotas for 1977 was reported at 175 million cubic meters for gas, 6.5 million tons for lignite, and 1.1 million tons for lignite briquets. In order to meet the increasing demand for lignite, 7 new mines are to be opened during the current 5-year plan period. About 60% of industrial investments in 1977 were used for the expansion of domestic energy and raw materials bases. Almost 75% of the total annual yield of 254 million tons of lignite is used by the Nation's approximately 80 power stations for the generation of electricity and heat. The G.D.R. provides 70% of its own energy raw materials requirements.[41]

The total capacity of the G.D.R.'s power stations reportedly amounted to 16,928 megawatts in 1975. In 1977, a total of 92 billion kilowatt-hours of electrical energy was produced. New large-scale thermal power stations have been equipped with block units produced in the Soviet Union. These units have a capacity of 210 or 500 megawatts each, and it is anticipated that more will be received from the Soviet Union.

According to some reports, the G.D.R. still uses the highest amount of electricity per inhabitant (5,015 kilowatt-hours in 1975), of all other CMEA countries, in spite of some successes in energy conservation. The G.D.R. also uses the most fuel in its production of power. The 5-year plan (1976-80) includes plans to lower the overall amount of energy used in industry by 5% annually and to lower use of electricity by 3%. Also, industrial production is planned to increase 6%.[42]

Nuclear energy is gaining in importance in the G.D.R. In 1977, there were three nuclear powerplants operating in the country, and two more are planned by 1980.

The total primary energy balance for 1976 and 1977 is shown in table 4.

Table 4.—German Democratic Republic: Total primary energy balance for 1976 and 1977

(Million tons of standard coal equivalent[1])

	Total primary energy	Coal (lignite, brown, bituminous)	Crude oil and petroleum products	Natural and associated gas	Hydroelectric power	Nuclear power
1976:						
Production[2]	94.3	74.6	0.1	18.8	0.2	0.6
Exports	5.0	1.4	3.5	--	.1	--
Imports	34.5	4.2	26.1	4.0	.2	--
Apparent consumption	123.8	88.4	22.7	22.8	.3	.6
1977:						
Production[2]	96.4	86.5	.1	19.0	.2	.6
Exports	6.9	2.0	4.1	--	.1	--
Imports	34.8	4.1	16.2	4.3	.2	--
Apparent consumption	125.0	78.6	22.2	23.3	.3	.6

[1]1 ton of standard coal equivalent (SCE)=7,000,000 kilocalories. Conversion factors used are: Hard coal, 1.0; lignite and brown coal, 0.3; crude oil, 1.47; natural gas, 1.33 (per thousand cubic meter); and hydroelectric and nuclear power, 0.125 (per thousand kilowatt-hours).

[2]Derived from table 1.

Source: World Energy Supplies, Statistical Papers, United Nations. New York. Ser. J, No. 18, 1975.

Coal.—The G.D.R. reportedly produced 28% of the world's lignite in 1977. 1978 production of raw lignite is projected at 254.4 million tons. The G.D.R. has 28,000 coal miners working in 35 open pits. Reportedly, 785 coal trains and almost 5,000 kilometers of track are used to transport this coal within the mines.[43] It was also reported that in 1977 the G.D.R. had 16 modern overburden conveyors, 240 heavy-duty excavators, and 60 spreaders.

Digitized by Google

The G.D.R. is also a major manufacturer of coal mine machinery. About 50% of the total world production of brown coal is extracted with machinery produced by VEB Tagebauausrustungen, Krane und Forderanlagen, commonly known as TAKRAF.[44] Despite its large market share, the company is little known outside Eastern Europe.

Lignite in the G.D.R. is now being produced under geological and hydrological conditions of increasing complexity. For example, in 1977 it was necessary to remove about 4 to 5 cubic meters of overburden in order to mine a ton of raw lignite. Removal of the same amount of overburden in 1960 yielded 2.8 tons of lignite. The G.D.R.'s lignite is also diminishing in quality. It contains increasingly more sulfur and salts, which are especially problematic for powerplants. Also, coal is now mined from greater depths. The average mining depth for lignite has increased from 80 meters in 1970 to 100 meters in 1977, and is expected to reach 140 meters in 1985. During the 1976-80 period, new mines with an output of 78 million tons would have to be opened to replace the presently diminishing output from the G.D.R.'s strip mines. The lignite reserves of the G.D.R. are estimated at 15 to 20 billion tons, and are expected to supply the needs of the Nation's thermal electric plants to the year 2000 and beyond. Meanwhile, the development of nuclear power is expected to continue.

In 1977, the G.D.R. reclaimed about 2,500 hectares of surface-mined land. Since reclamation efforts began, 50,000 hectares have been restored for use as cropland, and another 10,000 hectares are expected to be reclaimed by 1980. About 0.4% of the G.D.R.'s croplands and forested areas are affected by surface mining.[45]

Hard coal in the G.D.R. was extracted from only a few mines in the Zwickau area, with an average annual output of slightly less than 100,000 tons. Hard coal mining in the G.D.R. has practically ceased because deposits are depleted. The last shipment of hard coal from the Martin Hoop mine in the Karl-Marx-Stadt area was made last November. Some 50% of this mine's work force is expected to remain at the mine for the next few years, infilling the main shaft and retrieving secondary materials.[46]

The major lignite-producing areas in 1977 were the Schlabendorf Süd (South) and Witznitz surface mines, which recently started operations. The new Schlabendorf Süd mine (in the Cottbus District) is administered by the Jugend lignite enterprise and is the main supplier of lignite to the Luebbenau, Vetschau, and other power stations. The mine's targeted 1978 production is 18 million tons. The Jugend enterprise was also developing surface mines in 1977 at the Cottbus Nord (North) District and was expanding the capacity of its Greifenhain surface mine. The enterprise reportedly earned M74 million from these mines in 1977. In 1978, the enterprise plans to remove an extra 1 million cubic meters of overburden and produce a total of 34.5 million tons of lignite.

The open pit lignite mine of the Regis combine in the Groitsch Dreieck (Groitsch Triangle) was opened ahead of schedule in 1977. When fully developed in 1981, annual production from this mine is anticipated to reach 6.5 million tons of raw coal. This mine is expected to become a significant supplier beyond the year 2000. Lignite reserves of the Groitsch Dreieck area are estimated at 200 million tons.[47]

In December of 1977, the Weisse Elster River (in the Leipzig District) was rerouted into a new 12-kilometer-long artificial channel just south of Leipzig. The lignite reserves in the exposed riverbed are estimated at 300 million tons. The M325 million rerouting project was completed in less than 5 years and is one of the major investments of the G.D.R.'s coal and energy ministry. The Leipzig-Zeitz railway line was also renovated and rebuilt as a two-track line to accommodate new production from the Weisse Elster. The new Zwenkau strip mine is also expected to be productive to the year 2000.[48]

Natural Gas.—Most of the G.D.R.'s natural gas production comes from the Magdeburg field near the country's border with the F.D.R. Plans are for the production of gas from the Salzwedel gasfield in the Magdeburg District to be upgraded in order to minimize the need for expensive imported gas. It was reported that 2.1 million cubic meters of gas per day was produced from that field, compared with 1 million cubic meters production in 1970. The present natural gas reserves of the G.D.R. are estimated at about 100 billion cubic meters.

In 1977, deep wells were drilled at a new gasfield in northern Mecklenburg Province. The well structure may extend offshore into the Baltic Sea, but because of tight censorship, little is known of this exploration and

Digitized by Google

development program. Onshore, about 58% of the G.D.R.'s territory (63,000 square kilometers) is considered promising for potential discoveries of gas or oil.[49]

In order to meet domestic requirements, the G.D.R. imports gas from the Soviet Union. Such imports have increased repeatedly and in 1977 stood at over 3 billion cubic meters. Gas from the Soviet Union is transported through the Czechoslovakian gas-pipe system. Gas imports from the Soviet Union are expected to exceed 4 billion cubic meters in 1978, 6 billion cubic meters in 1979, and approach 7 billion cubic meters in 1980. The U.S.S.R. contracted to deliver 21.6 billion cubic meters of gas to the G.D.R. during the 1976-80 period. The Orenburg (Soyuz) gas pipeline is expected to nearly double the supply of Soviet gas to the G.D.R. when it is completed. Completion is scheduled for 1979. Under an agreement between the two countries, 2.8 billion cubic meters of natural gas per year will be piped to the G.D.R.

In 1977, the overall length of gas pipelines in the G.D.R. was 39,276 kilometers and underground gas-storage capacity was 170 million cubic meters. In the G.D.R.'s gas-pipe system, 715 kilometers of pipe are more than 50 years old and 67 kilometers are more than 100 years old. At the time these oldest pipes were laid down, gas was used primarily for cooking.[50]

The G.D.R. also manufactures coal gas at VEB Gaskombinat Schwarze Pumpe, a coal-gasification plant. The plant manufactures about 4 billion cubic meters of coal gas annually, or 25% of the G.D.R.'s total coal gas production.

Nuclear Power.—The G.D.R. produced about 5% of its electric energy, or 4.8 billion kilowatt-hours, from nuclear power. The country's development of nuclear energy has been slow, compared with its development in the West. Nonetheless, nuclear energy is gaining in importance in the G.D.R. By 1980, for example, the production of electric energy from nuclear power is expected to increase 26% as a result of the Nation's ongoing nuclear expansion.[51]

There were three operating nuclear plants in 1977. By 1978, a fourth unit is expected to be onstream. Nuclear plants that were operating in 1977 were the small 70-megawatt Rheinberg unit and two power station reactors with 440-megawatt capacities that are part of the Bruno Leuschner nuclear powerplant in Lubmin (in the Rostock District) near Greifswald on the Baltic coast. The fourth unit is expected to become operational in 1978, and three others are slated for operation by 1980.

Two 440-megawatt nuclear plants were under construction in 1977 in the Magdeburg District at Stendal. Construction and technical aid were again supplied by the Soviet Union. Completion of both units is scheduled for 1980.

The G.D.R.'s first nuclear plant was built near Rheinsberg in 1965. It is reported that the plant has an adverse effect on the ecology of Stechlin Lake because of its daily intake of 480,000 cubic meters of water. Furthermore, this water is also 10° warmer than normal when it is discharged back into the lake. It is planned that by 1980 the plant will discharge the heated outflow into nearby marshy wetland instead of into the lake.[52]

Petroleum.—The G.D.R.'s production of crude oil is estimated at approximately 7,000 barrels per day. Crude oil output comes from the Schwedt area and from a cluster of small fields near the Baltic Sea.

There are a total of 9 oil and oil-gas fields and 10 gas and gas-oil fields in the G.D.R. It was reported that Soviet orbiting satellites detected a number of potentially petroliferous structures along the G.D.R.'s Baltic coast and eastward into Polish territory. The presence of these structures was supposedly a decisive factor in a recent decision by Petrobalt (a cooperative enterprise including the G.D.R., Poland, and the U.S.S.R.) to order a Dutch jack-up rig for exploratory drilling in the Baltic.

There are four new oil fields close to the Baltic in the northern part of the Mecklenburg District, but no major oil discoveries have yet been reported. The largest of these fields is on Usedom Island, just west of the Polish border. The field extends into shallow water off the island's southern coast. The three other oil fields in the area are Rheinkenhagen, between the cities of Greifswald and Stralsund, and two fields just to the west and northwest, in the Greifswald-Stralsund-Grimmen Triangle. The Rheinkenhagen Field was discovered in 1961 and produces oil from Upper Permian beds from 2,300-foot depths. No data is available on the other three fields.

In 1977, the G.D.R. drilled a wildcat well at 8,000 meters, a new depth record for the country and for all of Europe. Romanian-built equipment was used to drill the well.

Digitized by Google

The well's location is not known, but it is believed to be in the area of the triangle. The G.D.R. has a number of rigs capable of drilling below 6,000 meters. Besides the 8,000-meter well drilled in the Mecklenburg District, for example, a hole in the Grimmen District was drilled to more than 7,000 meters as early as 1974.[53]

The G.D.R. in 1977 imported almost 95% of its crude petroleum, or approximately 17.7 million tons, from the Soviet Union, compared with 16 million tons of crude petroleum imports in 1976. Due to price increases, the G.D.R. reportedly paid 41 transfer rubles per barrel for its imports of Soviet oil.[54]

The total capacity of the G.D.R.'s refineries is the third largest of any European country after the U.S.S.R. and Romania and is estimated at 440,000 barrels per day. The G.D.R. has sufficient refining capacity to meet its own demand of about 336,000 barrels per day and to export 50,500 barrels per day of gasoline, diesel fuel, and fuel oil.

Runs at the G.D.R.'s newly expanded refinery at Schwedt on the Oder River near the Polish border amounted to nearly 204,000 barrels per day in 1977. The plant is located at the terminal of the "Friendship" pipeline and processes Soviet crude delivered across Poland by the pipeline. The Leuna refinery was expanding its refining capacity for light petroleum products in 1977. The refinery produces about 20% of the country's chemicals, 78% of its diesel fuel, 86% of its heating oil, and 72% of its liquid gas. The value of the Leuna refinery's production reached M10 billion in 1977. The Leunawerke employs 30,000 workers and is the G.D.R.'s largest industrial complex. Crude petroleum is processed in Böhlen, Zeitz, and Lützkendorf.

The Mineral Industry of the Federal Republic of Germany

By Joseph B. Huvos[1]

The Federal Republic of Germany (FRG) is one of the world's major processors and consumers of minerals, most of which are imported. There is, however, a plentiful supply of domestic coal, potash, and salt. National efforts are focused on securing and expanding raw material supply by encouraging development of domestic resources at the State level, concluding trade agreements, and encouraging foreign exploration, development, and operations. For this purpose, private industry is assisted by Government guarantees, loans, and special tax rates.

In 1977, the performance of the country's economy was disappointing in most respects. Lower-than-expected consumer and Government expenditures, and a slackening of export growth underlay the weakening of demand during the year.

In 1977, the gross national product (GNP) of the FRG was $529 billion[2 3]. The unemployment rate remained at about 4.5%. The contribution of the minerals industry to the GNP was about 11%. Contribution of the individual sectors of the minerals industry to the GNP in 1976 and 1977 is shown in the following tabulation:

Sector	Contribution to gross national product[1]			Average 1977 employment (thousand persons)
	Million dollars		Change (percent)	
	1976	1977		
Mining:				
Coal	6,415	7,316	+14	215
Iron ore	47	6	-87	1
Potash and salt	535	597	+12	12
Other	1,597	1,862	+17	6
Total	8,594	9,781	+14	234
Processing:				
Iron and steel	18,727	17,770	-5	306
Nonferrous metals	6,099	7,193	+18	78
Stone and earths	9,080	9,731	+7	183
Petroleum refining	16,353	21,221	+30	29
Nuclear fuel	68	101	+49	2
Total	50,327	56,016	+11	598

[1]Does not include value-added tax and production outside the territory of the Federal Republic of Germany.

Source: Adapted from Statistisches Bundesamt, (Wiesbaden), Wirtschaft und Statistik, No. 4, 1978, pp. 227-228.

Digitized by Google

In 1977, there were several major events in the FRG's mineral industry. Major plants commissioned included an all-hydraulic coal mine, a new nuclear powerplant, and a large-diameter-steel-pipe plant. There was a new gas discovery on the mainland, and natural gas started to flow from the Norwegian North Sea Ekofisk gasfields to the Federal Republic of Germany. A major iron ore mine and a barite mine closed. Large deficits in the steel industry brought about the beginning of a reorganization of the industry. The fuel oil tax was doubled, and funds were allocated for the purpose of saving energy. Bituminous coal was subsidized increasingly for electric powerplants and steel mills.

PRODUCTION

In 1977, production of most minerals declined with the exception of natural gas. Production of mineral commodities in 1976 and 1977 is shown in table 1.

Table 1.—Federal Republic of Germany: Production of mineral commodities

(Metric tons unless otherwise specified)

Commodity	1975	1976	1977[p]
METALS			
Aluminum:			
Bauxite, gross weight	755	221	28
Alumina thousand tons	1,246	1,333	1,454
Metal:			
Primary do	678	697	742
Secondary:			
Unalloyed do	38	42	45
Alloyed do	250	305	347
Bismuth:			
Ore and concentrate[e]	11	11	11
Metal, smelter[e]	600	500	700
Cadmium, smelter	1,018	1,275	1,336
Cobalt, smelter	340	250	350
Copper:			
Mine output, metal content	1,961	1,613	1,210
Metal:			
Blister and anodes:			
Primary	168,125	193,695	178,267
Secondary	47,722	50,805	58,407
Refined including secondary:			
Electrolytic	318,916	334,150	340,725
Fire, refined	103,286	112,431	99,431
Gold:			
Mine output, metal content troy ounces	2,116	2,456	2,392
Metal including secondary do	351,471	346,874	319,803
Iron and steel:			
Iron ore and concentrate thousand tons	3,288	2,256	2,470
Pig iron and blast furnace ferroalloys do	30,074	31,849	28,959
Electric furnace ferroalloys do	257	239	210
Steel ingots and castings do	40,415	42,415	38,985
Semimanufactures do	28,873	29,793	28,758
Lead:			
Mine output, metal content	32,383	31,675	31,105
Metal, unalloyed:			
Primary	92,242	100,965	105,150
Secondary	167,924	177,340	204,467
Magnesium metal and alloys:			
Unwrought (secondary only)	800	500	600
Castings	167,924	177,340	204,467
Mercury (secondary only) 76-pound flasks	3,191	3,191	[e]3,200
Molybdenum metal	179	227	NA
Nickel including secondary[1]	122	130	91
Platinum troy ounces	3,601	2,283	[e]4,820
Silver:			
Mine output, metal content thousand troy ounces	1,079	1,026	1,061
Metal including secondary do	20,417	23,497	18,004
Tin metal including secondary	2,332	2,254	3,940
Tungsten metal	894	1,563	[e]1,400

Table 1.—Federal Republic of Germany: Production of mineral commodities —Continued

(Metric tons unless otherwise specified)

Commodity		1975	1976	1977[p]
METALS —Continued				
Zinc:				
Mine output, metal content		116,072	115,344	114,152
Metal, unwrought, unalloyed, primary		294,725	304,754	341,582
NONMETALS				
Barite		[r]247,309	262,387	265,593
Bromine		4,270	4,154	3,736
Cement and clinker:				
Cement	thousand tons	[r]33,498	33,281	32,163
Clinker	do.	2,535	2,136	1,245
Clays:				
Fire clay (exclusive of klebsand)	do.	4,525	5,056	5,276
Kaolin (marketable)	do.	419	442	500
Bleaching	do.	599	628	642
Other (schieferton)	do.	90	108	129
Corundum, artificial		81,391	83,196	93,646
Diatomite and similar earth (marketable)		54,360	52,948	49,457
Feldspar (marketable)		395,833	419,976	393,793
Fertilizers:				
Crude:				
Phosphate rock	thousand tons	81	86	80
Potassic:				
Gross weight	do.	22,006	21,178	23,799
K_2O equivalent	do.	2,607	2,441	2,838
Manufactured:				
Nitrogenous (nitrogen content):				
Nitrogen fertilizers	do.	1,065	925	922
Mixed fertilizers	do.	387	322	381
Total	do.	1,452	1,247	1,303
Phosphatic (P_2O_5 content):				
Superphosphate	do.	43	40	43
Thomas slag fertilizers	do.	[r]202	167	134
Other phosphatic fertilizers	do.	[r]135	174	182
Mixed fertilizers	do.	378	317	364
Total	do.	758	698	723
Potassic K_2O equivalent:				
Marketable crude	do.	60	70	76
Chemically processed	do.	2,163	1,966	2,265
Total	do.	2,223	2,036	2,341
Content of mixed fertilizers[2]	do.	404	392	425
Mixed fertilizers, gross weight	do.	2,673	2,356	2,736
Fluorspar (marketable):				
Acid grade[e]		67,178	57,789	75,375
Metallurgical grade[e]		7,464	6,421	8,375
Total		74,642	64,420	83,750
Graphite:				
Crude		23,546	19,101	16,653
Marketable[3]		13,557	14,026	13,456
Gypsum and anhydrite, marketable	thousand tons	2,084	2,100	2,218
Lime, quicklime and hydrated lime, including dead-burned dolomite	do.	9,175	9,426	8,770
Pigments, natural mineral	do.	18	23	26
Pumice:				
Crude and washed	do.	3,584	3,689	3,137
Marketable	do.	1,915	2,197	1,749
Pyrite (marketable concentrate):				
Gross weight	do.	492	523	531
Sulfur content	do.	221	233	235
Quartz, quartzite, glass sand:				
Quartzite	do.	384	372	407
Quartz sand	do.	402	418	407
Quartz sand (unground) and glass sand	do.	5,669	6,111	6,737
Salt (marketable):				
Rock	do.	5,379	6,375	7,131
Marine and other	do.	3,937	4,942	5,192
Stone, sand and gravel, n.e.s:				
Dimension stone	thousand cubic meters	210	194	215
Limestone, industrial	thousand tons	52,574	52,615	48,953
Crushed and broken	do.	113,115	102,215	110,718
Slate[4]	do.	2	2	2
Basalt lava and lava sand	do.	6,894	5,922	6,623
Calcite	do.	7	4	9
Grinding stone	cubic meters	NA	48	63
Tuff	thousand tons	3	3	2

Table 1.—Federal Republic of Germany: Production of mineral commodities —Continued

(Metric tons unless otherwise specified)

Commodity	1975	1976	1977[p]
NONMETALS —Continued			
Stone, sand and gravel, n.e.s —Continued			
Industrial sands:			
Molding sand thousand tons	1,007	1,123	1,183
Other (klebsand) do	140	--	--
Sand and gravel do	171,476	155,010	170,425
Sulfur, elemental byproduct do	521	608	845
Talc, including talc schist do	21	18	16
MINERAL FUELS AND RELATED MATERIALS			
Carbon black	260,992	292,322	301,678
Coal:			
Anthracite thousand tons	7,651	6,628	6,067
Bituminous do	84,742	82,641	78,773
Lignite do	123,377	134,493	122,920
Total do	215,770	223,762	207,760
Coke:			
Metallurgical do	34,818	31,951	27,499
Gashouse do	1,250	971	809
Total do	36,068	32,922	28,308
Fuel briquets:			
Anthracite and bituminous do	1,697	1,357	1,305
Lignite do	4,984	4,390	4,104
Gas:			
Manufactured gas (excluding that from petroleum refineries):[5]			
Blast furnace gas million cubic feet	[r]201,293	201,399	174,312
Coke oven gas[6] do	288,414	263,517	223,294
Other gas do	[r]71,123	76,915	70,735
Total do	[r]560,830	541,831	468,341
Natural:			
Gross production do	645,445	665,537	678,565
Marketable production do	639,414	658,050	[e]670,000
Peat, agricultural use thousand tons	1,950	1,707	1,911
Petroleum:			
Crude thousand 42-gallon barrels	41,470	39,902	39,021
Refinery products:			
Gasoline, aviation and motor do	115,378	147,439	123,479
Jet fuel do	11,789	10,799	10,099
Kerosine do	257	378	456
Distillate fuel oil do	269,543	301,929	293,903
Residual fuel oil do	144,088	158,397	143,004
Lubricants do	8,444	9,081	6,763
Other:			
Liquefied petroleum gas do	26,498	32,680	38,741
Bitumen do	24,274	23,063	22,421
Unspecified do	90,132	98,534	86,999
Refinery fuel and losses do	35,762	38,230	46,253
Total do	726,165	820,530	772,118

[e]Estimate. [p]Preliminary. [r]Revised. NA Not available.

[1]Primary nickel and nickel contained in ferronickel, monel metal, and nickel oxide directly used by the steel industry.

[2]K_2O equivalent of potassic constiuent not added to K_2O equivalent of marketable crude and chemically processed potassic fertilizers because this would result in double counting.

[3]Produced in part from imported crude graphite.

[4]Exclusive of slate recovered from mine dumps.

[5]Natural gas equivalent, 240 kcal/ft3 (8400 kcal/m3).

[6]Includes water gas and generator gas from coke ovens.

Digitized by Google

TRADE

In 1977, the members of the European Community continued as the FRG's principal trading partners, but member states of the Organization of Petroleum Exporting Countries (OPEC) were also important. In 1977, the FRG had a trade surplus with the OPEC countries for the first time amounting to $760 million.

The FRG's commodity trade in 1976 and 1977 is shown in tables 2 and 3. Mineral commodities exported from the FRG included petroleum products, iron, steel, nonferrous metals, and nonferrous metal products. Mineral imports consisted principally of petroleum and natural gas, iron ore, nonferrous metal ores, and various industrial minerals.

Major mineral imports from the United States in 1976 included nuclear fuels, coal, nonferrous metals, and industrial minerals. Mineral exports to the United States included iron and steel semimanufactures, coke, and nonferrous metals. U.S.-FRG trade in 1976 is shown in table 4.

Table 2.—Federal Republic of Germany: Exports of mineral commodities

(Metric tons unless otherwise specified)

Commodity	1975	1976	Principal destinations,1976
METALS			
Aluminum:			
Bauxite	10,178	4,615	Belgium-Luxembourg 2,204; France 779; Austria 635.
Alumina	227,639	324,235	Canada 99,978; Spain 92,036.
Aluminum hydroxide	111,172	132,026	Netherlands 28,028; Sweden 27,488; Poland 20,046.
Metal including alloys:			
Scrap	r31,500	49,388	Netherlands 17,208; Italy 14,204; France 9,844.
Unwrought	159,658	281,426	Italy 70,350; France 65,488; Belgium-Luxembourg 40,399.
Semimanufactures	195,538	279,081	France 67,887; Netherlands 40,118; Belgium-Luxembourg 35,869.
Antimony:			
Ore and concentrate	7	--	--
Metal including alloys, all forms	111	75	Mozambique 26; Austria 18; United States 10.
Arsenic:			
Natural sulfides	4	7	NA.
Trioxide, pentoxide, acids	609	200	Italy 94.
Beryllium metal including alloys, all forms kilograms	8	(1)	NA.
Bismuth metal including alloys, all forms	401	526	United States 111; United Kingdom 109.
Cadmium metal (including rhenium), including alloys, all forms	408	477	NA.
Chromium:			
Chromite	3,014	13,551	Netherlands 8,025; Austria 3,151; France 1,137.
Oxide and hydroxide	7,147	10,142	NA.
Metal including alloys, all forms	r105	274	United States 101; Belgium-Luxembourg 44; Romania 30.
Cobalt:			
Oxide and hydroxide	7,147	67	Belgium-Luxembourg 33; Netherlands 8.
Metal including alloys, all forms	222	322	Sweden 59; Netherlands 44; United States 38.
Columbium and tantalum metals including alloys, all forms:			
Columbium kilograms	15,858	21,628	NA.
Tantalum	29,331	61,401	NA.
Copper:			
Ore and concentrate	(1)	77	NA.
Matte	1,182	212	NA.

Ferromanganese	40,730	45,918	Belgium-Luxembourg 18,275; France 8,156; United Kingdom 4,933.
Ferronickel	53	35	Yugoslavia 29.
Ferrosilicon	15,936	16,612	France 3,907.
Ferrosilicochrome	1,300	5,124	Italy 4,379.
Ferrosilicomanganese	567	2,052	Belgium-Luxembourg 1,164; France 540.
Other	r11,305	16,422	Romania 2,549; Italy 1,869.
Steel, primary forms thousand tons	2,345	2,171	France 677; Italy 300; Belgium-Luxembourg 279.
Semimanufactures:			
Bars, rods, angles, shapes, sections do	3,684	3,487	France 831; Netherlands 495.
Universals, plates, sheets do	5,268	4,845	U.S.S.R. 894; France 659.
Hoop and strip do	113	1,051	U.S.S.R. 165; Netherlands 143; France 140.
Rails and accessories do	278	204	Italy 50; Netherlands 30.
Wire do	286	276	France 59; Netherlands 48.
Tubes, pipes, fittings do	3,635	3,193	U.S.S.R. 746; People's Republic of China 385; Netherlands 370.
Castings and forgings, rough do	94	102	France 21; Belgium-Luxembourg 17; Netherlands 10.
Lead:			
Ore and concentrate	r3,434	7,094	Yugoslavia 3,876; Austria 2,101; Belgium-Luxembourg 1,117.
Oxides	8,880	12,759	Netherlands 6,069; Sweden 1,409.
Metal including alloys:			
Scrap	17,769	21,710	Italy 5,928; Netherlands 5,487; Belgium-Luxembourg 4,405.
Unwrought	80,902	72,198	Italy 36,004; France 1,2025.
Semimanufactures	8,662	9,184	Denmark 1,653; Switzerland 1,038.
Lithium:			
Ore and concentrate	186	505	Romania 221.
Oxides and hydroxides	517	544	France 157; Italy 129; Belgium-Luxembourg 75.
Metal, all forms	15	8	Switzerland 4; France 3.
Magnesium:			
Oxides, hydroxides, peroxides	3,063	4,453	Italy 1,304; U.S.S.R. 576; Austria 482.
Metal including alloys:			
Scrap	1,507	2,424	Italy 1,042; Netherlands 581; United Kingdom 253.
Unwrought	r233	194	Austria 68; France 54.
Semimanufactures	r336	299	Sweden 50; France 42; Netherlands 42.

Table 2.—Federal Republic of Germany: Exports of mineral commodities —Continued

(Metric tons unless otherwise specified)

Commodity	1975	1976	Principal destinations,1976
METALS —Continued			
Manganese:			
Ore and concentrate	r3,474	4,919	France 3,095; Netherlands 687.
Oxides	2,777	3,549	NA.
Metal	161	205	France 143.
Mercury 76-pound flasks	1,682	2,031	NA.
Molybdenum:			
Ore and concentrate	654	631	Belgium-Luxembourg 402; Sweden 139.
Metal including alloys, all forms	r206	263	NA.
Nickel metal including alloys:			
Scrap	3,013	5,682	Sweden 2,988; United Kingdom 741; Netherlands 701.
Unwrought	2,111	1,402	Netherlands 603; Switzerland 186; France 152.
Semimanufactures	13,676	15,189	United States 2,243; France 1,934; United Kingdom 1,617.
Platinum-group metals:			
Platinum:			
Ash and waste kilograms	--	29,929	France 9,601.
Scrap and sweepings troy ounces	376	1,174	Spain 1,013.
Metal including alloys, all forms do	r547,063	639,576	Italy 111,997; Netherlands 99,063.
Palladium metal including alloys, all forms do	246,221	204,781	Netherlands 67,903; Switzerland 54,123; United States 28,662.
Silicon metal	r1,052	600	Netherlands 237; France 145; United States 70.
Silver:			
Ash and waste kilograms	25,524	35,289	Belgium-Luxembourg 33,254.
Scrap and sweepings thousand troy ounces	37	18,734	Switzerland 16,216; Austria 2,502.
Metal including alloys do	31,616	35,387	Netherlands 5,234; France 4,342; Austria 2,502.
Tin:			
Ore and concentrate	--	1,014	All to United States.
Oxides	402	462	Brazil 69; France 57; United States 54.
Metal including alloys:			
Scrap	207	211	Netherlands 93; Denmark 49; United Kingdom 45.
Unwrought	1,716	2,203	Netherlands 774; France 456; United Kingdom 254.
Semimanufactures	823	805	Austria 63; Switzerland 46.
Titanium:			
Ore and concentrate	946	2,068	Austria 425; Netherlands 319; France 288.
Oxides	32,044	43,606	Italy 6,217; Netherlands 4,389; United States 4,292.
Metal including alloys, all forms	r1,579	1,411	France 329; Sweden 326; Italy 272.
Tungsten:			
Ore and concentrate	494	30	Belgium-Luxembourg 14; United Kingdom 13.
Metal including alloys, all forms	602	585	NA.
Uranium and thorium:			
Oxides, including rare earth oxides	803	689	United States 372; Japan 180.
Metals including alloys, all forms kilograms	r4,900	6,600	United States 1,400; Brazil 1,300; Belgium-Luxembourg 1,200.
Vanadium metal including alloys, all forms	30	(1)	NA.
Zinc:			
Ore and concentrate	r64,159	79,179	Belgium-Luxembourg 50,518; Netherlands 20,588.
Oxide	8,850	8,699	NA.
Metal including alloys:			
Scrap	6,934	5,245	Netherlands 2,815; Belgium-Luxembourg 1,020; Italy 658.
Blue powder	r5,110	5,615	Netherlands 1,445; Italy 1,353; Romania 951.
Unwrought	77,389	104,569	United States 45,587; Netherlands 13,724.
Semimanufactures	9,725	13,278	Netherlands 2,402; France 1,691.
Zirconium:			
Ore and concentrate	4,177	3,791	France 1,077; Italy 567; Netherlands 545.
Metal including alloys, all forms	104	85	United States 40; Japan 14.
Other:			
Ore and concentrate:			
Of columbium, tantalum, vanadium	776	921	United States 716; Japan 130.
Of base metals, n.e.s	21	(1)	NA.
Ash and residue containing nonferrous metals	147,935	182,541	Netherlands 73,235; Belgium-Luxembourg 37,047; Sweden 23,080.
Oxides, hydroxides, peroxides of metals,n.e.s	r14,706	14,321	Italy 1,348.

Table 2.—Federal Republic of Germany: Exports of mineral commodities —Continued

(Metric tons unless otherwise specified)

Commodity	1975	1976	Principal destinations,1976
METALS —Continued			
Other —Continued			
Metals including alloys, all forms:			
Metalloids:			
Arsenic and tellurium	7	12	Yugoslavia 7; United States 1.
Selenium and phosphorus[2]	10,380	12,182	NA.
Alkali, alkaline-earth, rare-earth metals	59	163	NA.
Pyrophoric alloys	90	61	NA.
Base metals including alloys, all forms, n.e.s	r571	592	France 230; Japan 156; Norway 86.
NONMETALS			
Abrasives:			
Natural:			
Pumice, emery, natural corundum, etc	633,595	388,454	Netherlands 291,734; Belgium-Luxembourg 77,073.
Dust and powder of precious and semiprecious stones kilograms	239	240	Brazil 146; Greece 69.
Grinding and polishing wheels and stones	r10,320	11,527	France 1,564; Netherlands 1,164.
Artificial:			
Corundum	30,807	35,769	Sweden 3,929; Netherlands 3,627; Italy 3,544.
Silicon carbide	16,894	21,038	NA.
Asbestos	77,770	67,953	Spain 8,346; France 7,954; Denmark 6,757.
Barite and witherite	46,992	65,582	Netherlands 32,721.
Boron materials:			
Crude natural borates	14,375	8,936	Italy 3,465; Sweden 2,954.
Oxide, acid, borates, perborates	26,754	38,485	Switzerland 19,574.
Bromine	269	203	Netherlands 152; Italy 46.
Cement thousand tons	2,071	2,078	Netherlands 1,446; Nigeria 164.
Chalk	13,589	15,693	Sweden 4,828; Netherlands 2,879; Denmark 2,430.
Clays and clay products (including all refractory brick):			
Crude:			
Andalusite and kyanite	5,482	2,695	Italy 661; Austria 443; Sweden 380.
Bentonite	32,856	48,335	France 15,173; Netherlands 10,431; Belgium-Luxembourg 10,183.
Ceramic clay	412,004	584,395	Netherlands 147,817; Italy 137,399; Belgium-Luxembourg 133,028.
Chamotte	31,152	36,972	Netherlands 15,183; Italy 7,522; Switzerland 5,397.
Dinas	14,299	15,882	France 3,837; Italy 3,406; Netherlands 2,650.
Fire clay	205,907	231,228	Italy 94,168; Netherlands 44,121; Belgium-Luxembourg 28,713.
Fuller's earth	402	226	NA.
Kaolin	108,378	97,734	Austria 31,296; Italy 20,086; Netherlands 14,297.
Other	280,835	278,213	Netherlands 219,789.
Products:			
Refractory (including nonclay brick)	683,554	636,392	France 125,714; Netherlands 43,461; Italy 43,382.
Nonrefractory	648,974	772,806	France 212,734; Belgium-Luxembourg 172,066; Netherlands 138,645.
Cryolite and chiolite kilograms	300	12,900	NA.
Diamond:			
Crude:			
Not set or strung thousand carats	r4	25	NA.
Other do	r125	134	Belgium-Luxembourg 46; Netherlands 36; Switzerland 15.
Industrial do	r123	191	Ireland 81; Netherlands 38; Switzerland 21.
Diatomite and other infusorial earth	r4,883	4,805	Netherlands 2,263; United Kingdom 867.
Feldspar, leucite, nepheline, nepheline syenite	10,849	14,744	France 4,062; Italy 2,144; Belgium-Luxembourg 1,609.
Fertilizer materials:			
Crude:			
Phosphatic	7,797	1,880	Madagascar 800; Switzerland 587; Netherlands 335.
Potassic	42,986	40,492	Belgium-Luxembourg 26,017; United Kingdom 8,830; Netherlands 5,441.
Manufactured:			
Nitrogenous thousand tons	950	1,091	Belgium-Luxembourg 379; Brazil 186.
Phosphatic do	83	36	Hungary 8; Ireland 8; Belgium-Luxembourg 7.
Potassic do	1,794	1,573	Belgium-Luxembourg 206; India 146; Denmark 136.
Other, including mixed do	678	489	France 119; Denmark 58; Belgium-Luxembourg 45.
Ammonia, anhydrous do	278	209	Denmark 110; Belgium-Luxembourg 44; United Kingdom 24.

Table 2.—Federal Republic of Germany: Exports of mineral commodities —Continued

(Metric tons unless otherwise specified)

Commodity	1975	1976	Principal destinations,1976
NONMETALS —Continued			
Fluorspar	r20,925	14,478	Austria 4,052; Belgium-Luxembourg 3,427; France 2,707.
Graphite, natural	6,107	7,284	Italy 2,154; United States 1,177.
Gypsum and plasters	286,121	272,025	Netherlands 166,485; Switzerland 33,173.
Iodine	28	36	Belgium-Luxembourg 14.
Lime	420,728	611,796	Netherlands 460,835; Belgium-Luxembourg 67,102; France 65,715.
Mica:			
Crude, including splittings and waste	r767	924	Switzerland 443; Austria 132.
Worked, including agglomerated splittings	204	269	United Kingdom 74; Denmark 28; Austria 25.
Pigments, mineral:			
Natural, crude	r3,236	3,008	Netherlands 770; United States 583.
Iron oxides, processed	r89,386	128,230	France 17,408; United States 17,231; United Kingdom 14,128.
Precious and semiprecious stones, except diamond:			
Natural kilograms	r320,024	249,055	Hong Kong 65,163; Japan 35,148; People's Republic of China 16,305.
Manufactured do	7,121	15,584	United States 8,176; Italy 2,254; Japan 1,958.
Pyrite (gross weight)	500	3,863	NA.
Salt thousand tons	1,589	1,821	Belgium-Luxembourg 1,259; Sweden 314.
Sodium and potassium compounds, n.e.s:			
Caustic soda do	946	1,007	Netherlands 149; Australia 88.
Caustic potash, sodic and potassic peroxides do	12	17	U.S.S.R. 8; United Kingdom 1.
Stone, sand and gravel:			
Dimension stone:			
Crude and partly worked:			
Calcareous	r2,867	2,504	Austria 1,517.
Slate	13,338	14,522	Netherlands 7,311; Belgium-Luxembourg 4,739; Denmark 1,482.
Other	459,035	508,575	Netherlands 359,339; Switzerland 125,645.
Worked:			
Slate	649	823	Netherlands 358; Belgium-Luxembourg 4,739; Denmark 1,482.
Paving and flagstone	9,052	12,923	Denmark 5,337; Belgium-Luxembourg 3,104; Netherlands 2,241.
Other	15,350	18,094	France 4,330; Belgium-Luxembourg 4,241; Netherlands 3,345.
Dolomite, chiefly refractory grade	r170,665	238,096	France 85,006; Netherlands 77,798; Belgium-Luxembourg 64,599.
Gravel and crushed rock thousand tons	r11,808	10,849	Netherlands 8,732; Belgium-Luxembourg 860.
Limestone (except dimension)	45,522	52,825	Netherlands 32,583; Belgium-Luxembourg 15,951.
Quartz and quartzite	59,937	85,186	Belgium-Luxembourg 33,348; Austria 15,838; Netherlands 9,940.
Sand, excluding metal bearing thousand tons	r7,366	6,728	Netherlands 5,691; Belgium-Luxembourg 580.
Sulfates, natural, magnesium sulfate (Kieserite)	445,473	439,194	Norway 68,646; France 61,602; Netherlands 53,601.
Sulfur:			
Elemental:			
Other than colloidal	199,018	144,197	Denmark 59,699; Switzerland 28,398.
Colloidal	2,516	2,420	United Kingdom 413; India 288.
Sulfur dioxide	15,019	13,272	Belgium-Luxembourg 6,227; Sweden 2,057; Austria 1,725.
Sulfuric acid, including oleum	r737,922	640,086	Netherlands 122,806; France 69,901.
Talc, steatite, soapstone, pyrophyllite	r5,748	7,057	Denmark 3,533; Belgium-Luxemburg 708.
Other:			
Crude:			
Meerschaum, amber, jet kilograms	r300	100	NA.
Pottery, broken	r22,401	26,324	Netherlands 15,138; France 4,856; Austria 3,743.
Pozzolan and Santorin earth	9,188	5,397	Switzerland 1,823; France 1,007.
Vermiculite, perlite, chlorite	473	693	NA.
Other thousand tons	r1,372	1,421	Netherlands 1,172.
Slag, dross, and similar waste, not metal bearing:			
From iron and steel manufacture do	2,328	2,589	Netherlands 2,511.
Slag and ash, n.e.s do	1,056	696	Netherlands 537; France 112.
Oxides and hydroxides of strontium and barium	r2,440	3,029	France 935; United States 723; Belgium-Luxembourg 459.

See footnotes at end of table.

Table 2.—Federal Republic of Germany: Exports of mineral commodities —Continued

(Metric tons unless otherwise specified)

Commodity	1975	1976	Principal destinations,1976
MINERAL FUELS AND RELATED MATERIALS			
Asphalt and bitumen, natural	2,667	2,416	Switzerland 454.
Carbon black and gas carbon:			
Carbon black	90,410	r88,844	France 18,097; Belgium-Luxembourg 11,927; Austria 11,080.
Gas carbon	209	139	NA.
Coal and briquets:			
Anthracite and bituminous coal thousand tons	14,468	12,805	France 4,529; Belgium-Luxembourg 3,784; Italy 2,378.
Briquets of anthracite and bituminous coal do	240	215	Belgium-Luxembourg 97; France 40; Austria 35.
Lignite and lignite briquets do	486	461	France 175; Austria 138; Belgium-Luxembourg 59.
Coke and semicoke do	r7,365	7,099	France 2,251; Belgium-Luxembourg 2,208; United States 852.
Hydrogen and other rare gases	19,500	22,061	Mainly to France and Italy.
Peat, including peat briquets and litter	398,901	422,701	Netherlands 261,928; Switzerland 55,248; France 46,757.
Petroleum:			
Crude thousand 42-gallon barrels	103	224	Mainly to Netherlands.
Refinery products:			
Gasoline, motor do	r5,725	3,457	Austria 1,888; Switzerland 55,248; France 46,757.
Kerosine and white spirit do	r9,614	10,013	Switzerland 634; Denmark 600.
Distillate fuel oil do	8,691	8,624	Switzerland 4,697; France 821.
Residual fuel oil do	r18,655	19,068	Austria 2,962; France 1,679 Belgium-Luxembourg 1,456.
Lubricants do	r2,675	3,031	Belgium-Luxembourg 629; United Kingdom 356; Sweden 334.
Mineral jelly and wax do	r931	1,105	Netherlands 108; Italy 102; Denmark 81.
Liquefied petroleum gas do	3,189	3,676	Belgium-Luxembourg 675; Netherlands 605; Italy 363.
Other do	13,580	15,456	France 4,686; Netherlands 3,647; Austria 1,194.
Mineral tar and other coal-, petroleum-, or gas-derived crude chemicals thousand tons	187	153	Netherlands 50; Belgium-Luxembourg 23.

rRevised. NA Not available.
[1]Less than 1/2 unit.
[2]Includes elemental sodium and potassium.

Table 3.—Federal Republic of Germany: Imports of mineral commodities

(Metric tons unless otherwise specified)

Commodity	1975	1976	Principle sources, 1976
METALS			
Aluminum:			
Bauxite ____ thousand tons	r4,213	4,087	Australia 2,239; Guinea 1,174.
Alumina	471,753	473,148	Australia 233,820; Italy 186,270.
Aluminum hydroxide	2,541	2,652	United States 1,733; France 760.
Metal including alloys:			
Scrap	r92,626	102,532	Netherlands 31,060; Austria 13,357; France 10,564.
Unwrought	r284,453	405,149	Norway 175,433; Netherlands 61,922; United Kingdom 36,152.
Semimanufactures	140,305	205,487	France 50,509; Belgium-Luxembourg 48,286; Netherlands 33,814.
Antimony:			
Ore and concentrate	2,129	3,514	Turkey 900; Republic of South Africa 894; Thailand 463.
Metal including alloys, all forms	841	1,064	Belgium-Luxembourg 601; People's Republic of China 169.
Arsenic hydroxide	957	690	Belgium-Luxembourg 214; Sweden 135; People's Republic of China 13.
Beryllium metal including alloys, all forms kilograms	496	552	United States 452.
Bismuth metal including alloys, all forms	259	246	United Kingdom 23.
Cadmium metal including alloys, all forms	631	1,140	Belgium-Luxembourg 310; Japan 283; North Korea 181.
Calcium metal including alloys, all forms kilograms	4,700	7,000	Peru 1,400; Belgium-Luxembourg 1,000; Netherlands 1,000.
Chromium:			
Chromite	561,035	547,293	Republic of South Africa 177,864; U.S.S.R. 152,449; Turkey 64,895.
Oxide and hydroxide	2,273	1,568	U.S.S.R. 1,018; Netherlands 238.
Metal including alloys, all forms	391	435	Japan 181; France 126; Belgium-Luxembourg 54.
Cobalt:			
Oxide and hydroxide	153	346	Belgium-Luxembourg 197; France 66; United Kingdom 41.
Metal including alloys, all forms	r1,482	1,870	Zaire 856; Belgium-Luxembourg 388.
Columbium and tantalum metals, including alloys, all forms:			
Columbium ____ kilograms	4,769	3,161	United States 2,811.
Tantalum ____ do	138,994	124,852	United States 107,546.
Copper:			
Ore and concentrate	564,352	615,285	Papua New Guinea 284,838; Norway 106,363; Indonesia 70,518.
Matte	2,051	1,027	Australia 518; United Kingdom 445.
Copper sulfate	6,349	9,752	France 5,932; U.S.S.R. 1,691.
Metal including alloys:			
Scrap	89,294	114,699	France 34,122; Netherlands 17,472; United Kingdom 14,563.
Unwrought:			
Smelter	119,850	130,790	Republic of South Africa 62,048; Chile 52, 156.
Refined	393,936	401,303	Chile 90,914; Zambia 81,150; Belgium-Luxembourg 55,901.
Alloys	39,086	47,345	United Kingdom 11,448; Poland 6,861.
Master alloys	1,235	2,221	United Kingdom 1,827; Belgium-Luxembourg 223.
Semimanufactures	115,190	144,137	Belgium-Luxembourg 51,901; France 40,803; Italy 15,901.
Gallium metal including alloys, all forms kilograms	4,700	7,000	Belgium-Luxembourg 1,000; Netherlands 1,000; Peru 1,000.
Gold metal:			
Ash and waste ____ do	96,946	47,646	United States 19,340; Switzerland 17,135.
Scrap and sweepings thousand troy ounces	1,154	831	Belgium-Luxembourg 226; Netherlands 152; Switzerland 149.
Metal:			
Unwrought ____ do	r2,127	2,922	Switzerland 1,639; Republic of South Africa 428.
Semimanufactures ____ do	r27	29	United States 13; Republic of South Africa 6; Switzerland 6.
Hafnium metal including alloys, all forms kilograms	2	--	
Iron and steel:			
Ore and concentrate ____ thousand tons	44,322	46,775	Brazil 12,075; Liberia 6,600; Canada 6,355.
Roasted pyrite ____ do	843	906	Spain 584; Belgium-Luxembourg 174; Portugal 112.
Metal:			
Scrap ____ do	1,720	1,545	Netherlands 746; Belgium-Luxembourg 206; France 202.
Pig iron including cast iron ____ do	158	292	Brazil 85; U.S.S.R. 73; Canada 47.

Table 3.—Federal Republic of Germany: Imports of mineral commodities —Continued

(Metric tons unless otherwise specified)

Commodity	1975	1976	Principle sources, 1976
METALS —Continued			
Iron and steel —Continued			
Metal —Continued			
Sponge iron, powder, shot thousand tons	38	39	France 19; Sweden 14; United Kingdom 6.
Spiegeleisen	503	301	NA.
Ferroalloys:			
Ferrochrome thousand tons	88	139	Republic of South Africa 91.
Ferromanganese do	157	174	Norway 78; France 48.
Ferronickel do	38	56	Greece 19; New Caledonia 19; Japan 9.
Ferrosilicon do	116	136	Norway 52; France 41.
Ferrisilicochrome do	13	20	Republic of South Africa 15.
Ferrisilicomanganese do	70	71	Norway 42; Republic of South Africa 13; Czechoslovakia 7.
Other do	r13	18	France 5; Belgium-Luxembourg 3; Brazil 2.
Steel, primary forms do	1,859	1,943	Belgium-Luxembourg 470; Netherlands 418; Austria 215.
Semimanufactures:			
Bars, rods, angles, shapes, sections do	2,690	3,857	Belgium-Luxembourg 1,347; Italy 640; France 468.
Universals, plates, sheets do	3,185	3,806	Belgium-Luxembourg 1,189; France 663; Austria 282.
Hoop and strip do	456	550	Belgium-Luxembourg 239; France 132; Netherlands 77.
Rails and accessories do	20	19	Netherlands 9; Sierra Leone 3; Sweden 3.
Wire do	r152	610	Belgium-Luxembourg 91; France 46.
Tubes, pipes, fittings do	538	685	Italy 142; Netherlands 120; France 97.
Castings and forgings, rough do	25	29	Romania 6; France 5; Netherlands 5.
Lead:			
Ore and concentrate	208,978	190,104	Sweden 54,109; Canada 28,356; United States 18,844.
Oxides	3,765	6,109	Belgium-Luxembourg 2,261; France 1,930.
Metal including alloys:			
Scrap	10,205	23,769	Netherlands 9,432; France 5,598; Belgium-Luxembourg 2,041.
Unwrought	122,829	110,453	Sweden 24,308; United Kingdom 20,973; North Korea 18,714.
Semimanufactures	1,885	2,465	Belgium-Luxembourg 1,155; France 502; Yugoslavia 424.
Lithium:			
Ore and concentrate	3,521	4,308	Republic of South Africa 3,747.
Oxides and hydroxides	r459	344	United States 177; U.S.S.R. 100.
Metal, all forms	26	17	United States 13.
Magnesium:			
Oxides, hydroxides, peroxides	3,409	5,450	France 1,337; Netherlands 1,124.
Metal including alloys:			
Scrap	r3,846	1,893	Netherlands 723; Austria 316.
Unwrought	r19,530	28,324	Norway 13,564; Italy 4,198; United States 3,761.
Semimanufactures	r567	425	United States 295.
Manganese:			
Ore and concentrate thousand tons	733	610	Republic of South Africa 358; Australia 144.
Oxides	1,449	2,169	Belgium-Luxembourg 1,508; Japan 287; Greece 241.
Metal	4,365	6,208	Republic of South Africa 2,726; France 1,180; Netherlands 1,088.
Mercury 76-pound flasks	r12,154	19,929	Italy 11,313; Algeria 5,831.
Molybdenum:			
Ore and concentrate	14,736	41,674	Australia 15,895; United States 11,920; Netherlands 4,357.
Metal including alloys, all forms	376	505	Austria 271; United States 107.
Nickel:			
Ore and concentrate	NA	2	NA.
Matte and speiss	6,550	13,820	Australia 8,419; Canada 4,208.
Metal including alloys:			
Scrap	6,453	7,408	France 1,448; United States 1,390.
Unwrought	36,387	43,080	United Kingdom 8,307; United States 8,188; Norway 7,941.
Semimanufactures	4,416	4,813	Australia 1,419; United Kingdom 905; France 790.
Platinum-group metals:			
Platinum:			
Ash and waste kilograms	275,580	199,801	Switzerland 111,218.
Scrap and sweepings thousand troy ounces	126	144	Belgium-Luxembourg 74; Netherlands 18; United States 14.
Metal including alloys, all forms do	286	315	UnitedKingdom 133; United States 57; U.S.S.R. 32.

See footnotes at end of table.

Table 3.—Federal Republic of Germany: Imports of mineral commodities —Continued

(Metric tons unless otherwise specified)

Commodity	1975	1976	Principle sources, 1976
METALS —Continued			
Platinum-group metals —Continued			
Palladium metal including alloys, all forms thousand troy ounce	368	631	United States 228; U.S.S.R. 198; United Kingdom 136.
Other metals including alloys, all forms do	77	58	Republic of South Africa 25; United Kingdom 21.
Silicon metal including alloys, all forms	294,120	45,243	Norway 14,792; France 11,963; Republic of South Africa 6,106.
Silver:			
Ash and waste kilograms	265,186	491,323	United States 270,703.
Scrap and sweepings thousand troy ounces	3,374	3,556	United States 644; United Kingdom 607; Belgium-Luxembourg 501.
Metal including alloys, all forms do	31,672	42,535	Belgium-Luxembourg 6,057; United Kingdom 5,482; United States 5,004.
Tin:			
Ore and concentrate	9,883	9,550	Bolivia 7,470; Peru 1,398.
Oxides	54	48	Japan 21; France 9; Italy 7.
Metal including alloys:			
Scrap	449	394	Netherlands 145; Poland 103.
Unwrought	13,957	16,290	Indonesia 4,576; Thailand 3,781; Malaysia 2,744.
Semimanufactures	609	1,198	Netherlands 1,079.
Titanium:			
Ore and concentrate	330,191	472,733	Norway 338,536; Canada 66,402; Australia 47,397.
Oxides	19,533	24,396	Belgium-Luxembourg 12,281; Netherlands 4,660; Italy 3,376.
Metal including alloys, all forms	3,483	3,298	U.S.S.R. 2,121; Japan 407.
Tungsten:			
Ore and concentrate	3,365	4,362	People's Republic of China 1,298; France 1,219.
Oxide and hydroxide	174	33	France 26; United Kingdom 5.
Metal including alloys, all forms	91	83	United States 37; Belgium-Luxembourg 10; Netherlands 9.
Uranium and thorium:			
Ore and concentrate	7	NA	
Compounds	3	22	All from France.
Uranium metal including alloys, all forms kilograms	42,900	78,100	United States 40,500.
Vanadium:			
Oxides, hydroxides, pentoxides	408	433	Finland 232; Republic of South Africa 88; United States 51.
Metal including alloys, all forms	5	7	Belgium-Luxembourg 4.
Zinc:			
Ore and concentrate	550,888	601,349	Canada 217,826; Republic of South Africa 94,131; Sweden 61,101.
Oxide and peroxide	4,374	5,546	France 2,196; Netherlands 1,074.
Metal including alloys:			
Scrap	5,414	6,339	United Kingdom 1,542; Denmark 1,326; Netherlands 1,066.
Blue powder	8,838	13,014	Belgium-Luxembourg 10,925.
Unwrought	90,535	133,778	Belgium-Luxembourg 73,128; Netherlands 15,239.
Semimanufactures	17,738	19,638	France 8,828; Netherlands 3,604; Yugoslavia 3,057.
Zirconium metal including alloys, all forms	332	348	United States 36.
Other:			
Ore and concentrate:			
Of columbium, tantalum, vanadium	2,097	1,651	Brazil 1,483.
Of base metals, n.e.s	4,143	3,957	Australia 3,752.
Ash and residue containing nonferrous metals	277,449	381,594	Canada 125,052; Italy 32,070; United Kingdom 23,886.
Oxides, hydroxides, peroxides of metals, n.e.s	3,873	5,068	Belgium-Luxembourg 1,817; United Kingdom 821.
Metals including alloys, all forms:			
Metalloids:			
Arsenic and tellurium	32	61	Belgium-Luxembourg 15; U.S.S.R. 12; Sweden 10.
Selenium and phosphorus	18,349	23,738	NA.
Alkali, alkaline-earth, rare-earth metals	269	495	France 349.
Pyrophoric alloys, all forms	r836	30	NA.
NONMETALS			
Abrasives:			
Natural:			
Pumice, emery, natural corundum, etc	34,939	21,505	Greece 11,462; Italy 5,289; United States 2,421.
Dust and powder of precious and semiprecious stones kilograms	1,242	1,496	United States 824; Ireland 483.
Grinding and polishing wheels and stones	4,655	5,896	Austria 1,266; Spain 921; Italy 795.
Artificial:			
Corundum	22,634	28,510	Netherlands 9,747;Austria 4,789; Hungary 4,540.
Silicon carbide	49,557	61,450	Norway 12,670.

See footnotes at end of table.

Table 3.—Federal Republic of Germany: Imports of mineral commodities —Continued

(Metric tons unless otherwise specified)

Commodity	1975	1976	Principle sources, 1976
NONMETALS —Continued			
Asbestos	386,188	382,570	Canada 289,096; U.S.S.R. 41,296.
Barite and witherite	91,156	124,162	NA.
Boron materials:			
Crude natural borates	116,951	114,347	United States 72,823; Turkey 38,759.
Oxide and acid	11,623	13,854	France 5,900; Turkey 2,687; United States 2,589.
Bromine	1,805	3,110	Israel 2,601.
Cement thousand tons	540	627	France 274; Belgium-Luxembourg 144; Netherlands 95.
Chalk do	69	76	France 69.
Clays and clay products (including all refractory brick):			
Crude:			
Bentonite thousand tons	44	93	United States 67; Greece 11.
Ceramic clays:			
Kaolin do	555	653	United Kingdom 388; United States 95; Czechoslovakia 92.
Other do	109	140	Czechoslovakia 51; Netherlands 34; France 31.
Fire clays:			
Raw do	85	62	Czechoslovakia 17; Republic of South Africa 15; France 12.
Burned, including chamotte do	182	172	Czechoslovakia 71; United States 48; France 22.
Fuller's earth do	9	9	United States 4; Spain 4.
Kyanite, sillimanite, andalusite, mullite do	24	33	United States 17; France 5; Republic of South Africa 3.
Other do	41	61	Netherlands 30; France 17.
Products:			
Refractory (including nonclay brick) do	245	235	Austria 77; Czechoslovakia 31; France 27.
Nonrefractory do	1,048	1,278	Netherlands 505; Italy 367; France 148.
Cryolite and chiolite	1,955	4,578	Denmark 3,418; Greenland 1,142.
Diamond:			
Gem:			
Crude or rough cut thousand carats	70	80	NA.
Other do	11,810	7,935	Brazil 3,210; Republic of South Africa 1,330; Madagascar 935.
Industrial do	860	770	Republic of South Africa 305; Belgium-Luxembourg 220; Netherlands 110.
Diatomite and other infusorial earth	87,261	70,896	Denmark 38,807; Belgium-Luxembourg 16,244.
Feldspar, leucite, nepheline, nepheline syenite	102,585	101,785	Norway 77,811; Italy 10,181.
Fertilizer materials:			
Crude:			
Nitrogenous	NA	1,043	NA.
Phosphatic thousand tons	2,292	2,370	United States 1,135; Morocco 588; U.S.S.R. 495.
Manufactured:			
Nitrogenous	866,567	1,167,000	Belgium-Luxembourg 541,326; Netherlands 247,359; Romania 98,121.
Phosphatic	735,623	980,913	Belgium-Luxembourg 737,174; Tunisia 84,178.
Potassic	61,211	76,559	France 71,264.
Mixed	340,766	446,987	Belgium-Luxembourg 142,087; France 123,764; United Kingdom 72,814.
Fluorspar	261,094	244,643	Spain 31,310; Italy 30,913.
Graphite, natural	26,043	29,665	Austria 6,231; People's Republic of China 4,006; Norway 3,883.
Gypsum and plaster	303,321	411,394	France 177,815; Austria 137,824.
Iodine	864	814	Japan 657; Chile 127.
Magnesite	403,344	260,684	Greece 101,500; North Korea 33,233; Italy 31,416.
Mica:			
Crude, including splittings and waste	8,008	8,058	India 1,738; Republic of South Africa 1,378; Argentina 1,228.
Worked, including agglomerated splittings	599	615	France 309; Belgium-Luxembourg 227.
Pigments, mineral:			
Natural, crude	1,876	2,155	Austria 1,778; France 292.
Iron oxides and hydroxides	2,849	3,414	Netherlands 1,541; United States 340.
Precious and semiprecious stones, except diamond:			
Natural kilograms	9,530	8,318	India 2,321; Taiwan 1,084.
Manufactured do	22,551	27,323	Switzerland 16,911.
Pyrite (gross weight) thousand tons	498	175	U.S.S.R. 70; Spain 67; Norway 21.
Salt	641,976	776,954	Netherlands 641,775; France 98,535.
Sodium and potassium compounds, n.e.s.:			
Caustic soda	128,323	520,237	Belgium-Luxembourg 363,833; Netherlands 79,820.
Caustic potash, sodic and potassic peroxides	NA	10,888	Czechoslovakia 1,976; Sweden 1,789.
Stone, sand and gravel:			
Dimension stone:			
Crude and partly worked:			
Calcareous	192,518	159,671	Austria 57,818; Italy 41,222.

See footnotes at end of table.

Table 3.—Federal Republic of Germany: Imports of mineral commodities —Continued

(Metric tons unless otherwise specified)

Commodity	1975	1976	Principle sources, 1976
NONMETALS —Continued			
Stone, sand and gravel —Continued			
Dimension stone —Continued			
Crude and partly worked —Continued			
Slate	13,290	17,572	United Kingdom 6,289; Portugal 3,637; Spain 1,941.
Other	343,496	298,182	Denmark 52,511; Sweden 49,525; Austria 45,244.
Worked:			
Building and monumental stone	407,946	447,192	Italy 397,935.
Paving, flagstone, related materials	135,510	117,611	Portugal 60,613; Italy 15,555; Poland 12,087.
Slate	9,181	11,278	Spain 5,202; Italy 1,959; France 1,378.
Dolomite, including burned	684,877	662,417	Belgium-Luxembourg 593,578.
Gravel and crushed rock thousand tons	16,084	13,815	France 8,096; Denmark 2,204.
Limestone do	1,446	1,621	Austria 963; Sweden 248; Belgium-Luxembourg 229.
Quartz and quartzite:			
Quartz, crystal kilograms	479	116	Japan 81.
Other	127,381	98,412	Belgium-Luxembourg 32,362; Sweden 22,233; Yugoslavia 11,620.
Sand, excluding metal bearing thousand tons	3,086	2,609	France 1,978; Netherlands 363.
Sulfates, natural: Magnesium sulfate (Kieserite)	NA	10	NA.
Sulfur:			
Elemental:			
Other than colloidial	303,908	480,574	Poland 250,574; Canada 105,253; United States 63,370.
Colloidial	519	461	France 389.
Sulfur dioxide	1,275	1,322	Poland 894; Switzerland 408.
Sulfuric acid	43,918	68,551	France 16,841; Netherlands 11,553; Switzerland 8,449.
Talc, steatite, soapstone	87,517	111,223	Austria 42,106; Italy 17,332; France 16,170.
Vermiculite, chlorite, perlite	94,103	100,071	Greece 72,314; Hungary 13,154; Republic of South Africa 12,262.
Other:			
Crude:			
Meerschaum, amber, jet	9,267	17,372	Spain 17,342.
Pottery, broken	68,982	64,529	Netherlands 23,278; France 12,611; U.S.S.R. 6,644.
Other	445,154	566,478	France 235,505; United Kingdom 119,144; Austria 62,049.
Slag, dross and similar waste, not metal bearing:			
From iron and steel manufacture thousand tons	1,527	1,455	Belgium-Luxembourg 736; France 567.
Slag and ash, n.e.s do	183	199	France 113; Belgium-Luxembourg 53.
Oxide and hydroxide of strontium and barium	120	647	France 392; Netherlands 115.
MINERAL FUELS AND RELATED MATERIALS			
Asphalt and bitumen, natural	19,253	21,605	Trinidad and Tobago 12,983; United States 7,324.
Carbon black	30,001	45,894	Netherlands 16,770; France 15,644.
Coal and briquets:			
Anthracite and bituminous coal thousand tons	6,244	5,970	Poland 2,137; United States 1,094; South African Customs Union 672.
Briquets of anthracite and bituminous coal do	4	NA	
Lignite and lignite briquets do	1,647	1,565	Czechoslovakia 1,556.
Coke and semicoke do	1,283	1,266	United States 250; France 196; United Kingdom 128.
Gas, natural do	23,702	26,693	NA.
Peat and briquets do	24	45	U.S.S.R. 32; Netherlands 6; Poland 6.
Petroleum:			
Crude and partly refined thousand 42-gallon barrels	618,898	723,865	Libya 160,814; Saudi Arabia 137,756; Iran 132,793.
Refinery products:			
Gasoline, motor spirit do	34,060	29,036	Netherlands 11,552; Belgium-Luxembourg 3,596; Romania 3,456.
Kerosine, white spirit do	10,292	13,322	Netherlands 8,207; Belgium-Luxembourg 2,221.
Distillate fuel oil do	143,918	162,770	Netherlands 76,316; U.S.S.R. 29,855; France 11,324.
Residual fuel oil do	31,042	34,998	Netherlands 19,827; France 4,405; Belgium-Luxembourg 2,779.

COMMODITY REVIEW

METALS

Aluminum.—Reynolds Aluminium Deutschland, Inc. (RADI) concluded an installment purchase agreement with the city of Hamburg for the acquisition of the city's share of their jointly owned plant.

Vereinigte Aluminium Werke completed plans to rebuild its 55,000-ton-per-year Töging reduction plant. When work is completed in 1980, at a cost of $90 million, the plant's capacity will be 71,000 tons per year.

Production of primary and secondary aluminum increased in 1977; production costs also increased because of the higher cost of energy used in the production process. Average utilization of reduction plant capacity in 1977 was 98%. The FRG remained a net importer of aluminum metal.

In 1977, 10 reduction plants with a total nominal capacity of about 762,000 tons per year were operated. Approximately one-half of the country's aluminum supply was domestically produced primary metal, about one-quarter was secondary metal of domestic origin, and the rest was imported.

FRG primary aluminum producers, with plant capacity at the end of 1977, are shown in the following tabulation:

Company, ownership (in parentheses), and plant location	Yearend capacity 1977 (thousand tons)
Aluminium-Hütte Rheinfelden GmbH (Swiss Aluminium Co.[1]), Rheinfelden, Baden	64
Gebrüder Giulini GmbH, Ludwigshafen	45

Martinswerk GmbH für Chemische und Metallurgische Produktion (ALUSUISSE 92%), Bergheim	350
Gebrüder Giulini GmbH, Ludwigshafen	140
Total	1,730

Iron Ore.—The FRG's small iron ore production increased slightly in 1977. Local steel mills continued to rely on richer and cheaper imported ores.

At the end of 1977, Stahlwerke Peine-Salzgitter AG closed its Legende mine in Lower Saxony. The mine had produced 1.5 million tons of crude ore in 1977. The closing of the mine left the country with four iron ore mining companies and only six operating iron ore mines, as follows: Salzgitter Erzbergbau AG with a mine at Haverlahwiese, Barbara Rohstoffbetriebe mbH with mines at Fortuna and Wohlverwahrt-Nammen, Eisenwerk-Gesellschaft Maximilianshütte mbH with mines at Auerbach and Sulzbach-Rosenberg, and Stahlwerke Peine-Salzgitter AG with a mine at Bülten-Adenstedt.

Iron and Steel.—The worldwide economic recession and overcapacity in every major steel-producing country had a strong effect on the FRG's steel industry in 1977. Production was lower than at any time during the last decade, and the industry operated at only approximately 60% of capacity. Losses were around $200 million for the Dutch-FRG-Estel-Hoesch-Hoogovens Group, $130 million for Klöckner-Werke AG, and $90 million for Stahlwerke Röchling-Burbach GmbH in the Saar. Only the Thyssen Group, the world's ninth largest steel producer and Europe's largest privately owned steel company, managed to avoid an operating deficit.

A rationalization plan was prepared for the steel industry of the Saar, led by the Luxembourg-based Acíeries Réunies de Burbach-Eich-Dudelange (ARBED) concern.

Digitized by Google

The plan is expected to eliminate 8,800 jobs by 1983. To counteract possible unemployment, the Federal and the State Governments concurrently approved a Special Program for the Saar, creating new jobs outside the steel industry. In the program about $100 million was earmarked for 1978-81, and about 15,570 new jobs were to be created.

Klöckner Werke decided to cut its workforce by about 1,500 persons at its Georgsmarienhütte and Maxhütte works in Bremen. There had been short shifts at the company since February 1977.

Mannesmann-Röhren-Werke inaugurated a 1.1-million-ton-per-year large-diameter pipe mill at Mühlheim near Cologne.

It was reported that Stahlwerke Röchling-Burbach increased its holdings in Lech-Stahlwerke, the former Bayerische Elektrostahlwerke, to slightly over 89%.

Thyssen AG ordered from Krupp-Koppers GmbH an iron-ore-sintering plant with 250 square meters of surface and a capacity of 10,000 tons per day. The plant, valued at over $50 million, was to be located in Duisburg-Schwelgen.

FRG steel companies continued to be heavily involved in the Brazilian steel industry, both as owners and operators of steelmaking facilities and as suppliers of equipment for Brazilian steel plants. Companies involved included Mannesmann AG and Thyssen, both of Düsseldorf, Friedrich Gustav Theis Kaltwalzwerke GmbH of Hohenlimburg, Gutehoffnungshütte Sterkrade AG of Oberhausen, and Schloemann-Stemag AG and Maschinenfabrik Sack GmbH, both also of Düsseldorf.

In 1977, major FRG steel producers and approximate steelmaking capacities were as shown in the following tabulation:

Company	Capacity (million tons per year)
August Thyssen-Hütte AG	16.5
Hoesch AG	7.2
Klöckner-Werke AG	7.2
Peine-Salzgitter AG	6.3
Friedrich Krupp GmbH	4.5
Mannesmann AG	4.5
Stahlwerke Röchling-Burbach GmbH	2.8
AG der Dillinger Hüttenwerke	2.0
Neunkircher Eisenwerk AG	1.3

Lead, Zinc, Silver, Copper.—Preussag AG ordered short-shift work at its Grund and Rammelsberg mines and its Harz smelter in Lower Saxony. Reason for the measures was a collapse of zinc prices and demand.

Metallgesellschaft AG, also under the influence of the zinc market slump, ordered cutbacks in the output of its Ruhr zinc smelters, including the Duisburg and Datteln electrolytic plants.

At the end of 1977, four lead and zinc mines and five concentrators continued to operate in the FRG. In 1977, about 2 million tons of ore with 7% lead and zinc was mined. About one-half the lead-zinc ore was produced by Preussag AG in the Harz region, about 40% by Sachtleben Bergbau GmbH at Lennestadt in North Rhine-Westphalia, and 10% by AG Altenbergs für Bergbau und Zinkhüttenbetrieb at Lüderich near Cologne.

Zinc smelters and capacities at the end of 1977 are shown in the following tabulation:

Company and plant location	Type	Annual slab zinc capacity (thousand tons)
Berzelius Metallhütten GmbH, Duisburg-Wanheim.	Imperial	80
Duisburger Kupferhütte GmbH, Duisburg.	Electrothermic	20
Preussag-Weser-Zinc GmbH:		
Harlingerode	Vertical retort.	95
Nordenham	Electrolytic	110
Ruhr-Zinc GmbH, Datteln	do	130
Total		435

Lead smelting and refining works and capacities at the end of 1977 are shown in the following tabulation:

Company	Plant location	Annual refined lead capacity (thousand tons)
Berzelius Metallhütten GmbH	Duisburg-Wanheim.	[1]35
	Braubach	70
	Binsfeld-hammer.	80
Norddeutsche Affinerie	Hamburg	45
Preussag-Boliden-Blei GmbH	Nordenham	120
Preussag AG Metall	Oker (Harz)	45
Total		395

[1]Smelter only; bullion shipped to the company at Braubach.

Digitized by Google

The country's lead-zinc mines also produced moderate amounts of copper and silver as byproducts. Domestic copper and imported materials were processed and refined mainly in Norddeutsche Affinerie's 215,000-ton Hamburg refinery, Duisburger Kupferhütte's 30,000-ton Duisburg smelter, and Hüttenwerke Kayser AG's 15,000-ton Lünen smelter. There were also several smaller copper smelters and refiners.

Silver production was processed mainly at Preussag-Boliden-Blei GmbH's Nordenham lead smelter and Berzelius Metallhütten GmbH's Duisburg-Wanheim refinery.

NONMETALS

Barite.—In September 1977, the world's largest barite mine, Sachtleben Bergbau GmbH's Meggen facility near Lennestadt in central Germany, was closed owing to depletion of ore.

At the end of 1977, the FRG had six operating barite mines. Deutsche Baryt Industrie and Sachtleben controlled two each, and Feldhaus Schwerspatgrube GmbH and Preussag AG Metall controlled one each.

Cement.—After a slight increase during 1976, FRG cement consumption fell 4.8% in 1977, owing to a continued slump in the building industry. In 1977, the FRG, including West Berlin, operated 71 cement plants controlled by 42 individual companies.[4]

Fertilizer Materials.—*Nitrogen.*—Nitrogen production decreased further in 1977. Ammonia production ran at about 77% of capacity. Companies engaged in the production of ammonia, with their plants and capacity in 1977, are shown in the following tabulation:

Company	Plant location	Approximate capacity (thousand tons per year)
Badische Anilin und Soda Fabrik AG (BASF)	Ludwigshafen	800,000
Erdölchemie (Bayer, BP)	Cologne	300,000
Gewerkeschaft Viktor Chemische Werke	Castrop-Rauxel.	250,000
Hoesch AG	Frankfurt	115,000
Rheinische Braunkohlen-werke (URBK)	Wesseling	[1]360,000
VEBA-Chemie AG	Bottrop	145,000
	Herne	240,000
	Gelsenkirchen-Scholven.	400,000
	Brunsbüttel	[2]400,000

[1]In planning stage.

Source: Petroleum Times. V. 81, No. 2060, Sept. 30, 1977, pp. 51-53.

Phosphate.—Production of phosphate ore in the FRG ceased following the permanent closure of Stahlwerke Peine-Salzgitter AG's Legende iron ore mine at yearend 1977.

Potash.—As a result of a slight improvement in the international potash market, the FRG's potash production and sales improved somewhat but still remained lower than total capacity.

About 91% of potash output was produced by the nine potash mines of Kali und Salz AG: Bergmannsegen-Hugo, Hattorf, Neuhof-Ellers, Niedersachsen-Riedel, Salzdetfurth, Siegfried-Giesen, Sigmundshall, Wintershall, and Hope. The Hope a, small mine, is expected to be depleted by 1980, and its production and personnel were combined with those of the Sigmundshall mine. The second largest potash company, Kali-Chemie AG, accounted for the remaining 9% of the country's potash production at its Friedrichshall mine. All the FRG's potash mines were located in the Hannover area with the exception of Wintershall and Hattorf, which were east of Kassel on the East German border, and Neuhof-Ellers, which was near Fulda.

Fluorspar.—In 1977, fluorspar production increased. The domestic product supplied most of the FRG's chemical and ceramic industries. Metallurgical-grade spar was mainly imported. There were nine fluorspar mines in the FRG in 1977, operated by three companies: Flussspat Bergbau Paul Freitag (one mine); Fluss- und Schwerspat Werke Pforzheim (five mines); and VAW Flussspat-Chemie GmbH, Stulln (three mines). Almost all the mines were

Digitized by Google

located in Bavaria and Baden-Württemberg.

Salt.—Salt production increased in 1977 due to greater foreign and domestic demand for salt used in deicing roads. In 1977, 10 companies controlled 14 salt mines in the FRG: 8 of the mines produced rock salt, and the remaining 6 produced brine by solution mining. Kali und Salz controlled the rock salt mines of Mariaglück, Niedersachsen-Riedel, and Braunschweig-Lüneburg located in the Hannover area. Südwestdeutsche Salzwerke AG controlled the solution mine and refinery of Friedrichshall-Kochendorf and the Heilbronn rock salt mine in northern Baden-Württemberg. Deutsche Solvay Werke GmbH controlled Borth, a rock salt mine located in the western Ruhr area. Wacker Chemie AG controlled the Stetten rock salt mine, located south of Stuttgart, and Bayerische Berg-, Hütten- und Salzbergwerk AG controlled the Berchtesgaden rock salt mine, located on the border with Austria.

The following salt mines were all of the solution-mining type: Dow Chemical GmbH's Stade mine, northwest of Hamburg; Norddeutsche Salinen GmbH's Lüneburg mine, south of Hamburg; Salzgewinnungsgesellschaft Westfalen mbH's Epe mine, near the Netherlands border; Bartold Levin GmbH & Co. KG's Luisenhall mine, near Göttingen; Bayerische Berg-, Hütten- und Salzbergwerke AG's Reichenhall mine at Berchtesgaden; and Dynamit Nobel AG's Rheinheim mine on the Swiss border.

MINERAL FUELS

Domestic coal, coke, natural gas, and crude oil supplied about 38% of FRG's energy requirements. Imported petroleum, natural gas, and nuclear power accounted for the remaining portion.

Energy-saving measures instituted by the Government in 1977 included the doubling of the tax on heating oil to 3.8 cents per gallon, and $2 billion was allocated for various other measures for the 1978-82 period. A law on modernization of housing is to grant subsidies to homeowners for energy-saving installations.

Supply and apparent consumption of fuel and power in the FRG in 1976 and 1977 are shown in table 5.

Table 5.—Federal Republic of Germany: Supply and apparent consumption of fuels and power

(Million tons of standard coal equivalent[1])

	Total energy	Coal and coke	Petroleum and refinery products	Natural gas	Fuelwood and peat	Hydroelectric power	Nuclear power[2]	Other[3]
1976:								
Production[4]	160.8	125.9	8.0	21.2	0.4	4.1	--	1.2

Digitized by Google

Coal.—In 1977, coal production (bituminous and anthracite) fell further while sales decreased from 88.8 to 80 million tons. At the mines stocks of coal and coke grew by yearend to about 7 million tons and 12 million tons, respectively. The extremely weak demand for coal from steel mills, compounded by low economic growth and unfavorable weather conditions, accounted for the poor sales performance in 1977. There were no indications of a major improvement in the situation in the near future. Lasting recovery is hoped for only in the early or mid-1980's and if there is a worldwide energy shortage.

Lignite production decreased also in 1977. Development continued at Rheinische Braunkohlenwerke AG's Hambach mine.

Financial aid for the coal industry amounted to about $2 billion per year, including an approximately $1 billion surcharge paid by German electric power consumers to the utilities for the use of domestic coal in powerplants. Furthermore, the amount of public subsidies is expected to accelerate with an eye to promoting the use of such coal by the steel mills of the European Community.

Ruhrkohle AG converted its Hansa mine, located near Dortmund, to all-hydromechanical operation at a cost of about $60 million. Water is used to mine and transport coal to the surface.

The mines and steelworks of the Saar plan to build a central coking plant of 1.6 million tons per year capacity; construction costs are expected to be $300 million.

In 1977, there were 43 coal mines, 21 coking plants, 5 briquetting plants, and 29 mine-mouth powerplants in the country.[5] The industry was controlled mainly by seven companies: Three in the Ruhr, two in the Aachen area, and one each in Saarland and Lower Saxony. The largest industrial group was Ruhrkohle AG, controlling about three-quarters of the country's output.

The lignite industry was dominated by the Rheinische Braunkohlenwerke AG, which accounted for nearly four-fifths of total output; the remaining production came from two medium-sized and four smaller companies.

The FRG's bituminous coal reserves were estimated in 1974 at 44 billion tons, of which 30 billion tons was recoverable. Total resources were set at 230.3 billion tons. Known lignite reserves were placed at 55.5 billion tons, of which 9.5 billion tons was recoverable. Total resources were set at 55.9 billion tons.[6]

Nuclear Power.—The FRG's nuclear powerplants supplied one-third more electricity in 1977 than in 1976. The rise was due to the fact that this was the first complete operational year for the Biblis B, GKN-I, and KKB reactors. The KKI reactor, commissioned by yearend, contributed only a small amount. Two other plant completions that went on-line included KKU Unterweser (1,300 MWe) and KKP-1 Philippsburg (900 MWe).

In December 1977, the following 14 nuclear reactors were in operation in the FRG:

Name	Location	Capacity, nominal (Megawatts electrical)
VAK	Kahl	15
MZFR	Karlsruhe	57
KRB	Grundremmingen	252
AVR	Jülich	15
KWL	Lingen	168
KWO	Obrigheim	345
KKS	Stade	622
KWW	Würgassen	670
KNK	Karlsruhe	21
Biblis A	Biblis	1,204
Biblis B	do.	1,300
GKN-1	Neckarwestheim	855
KKB	Brunsbüttel	806
KKI	Isar	907

In addition, 12 plants with a total capacity of 14,360 MWe were under construction, and 12 plants totaling 15,229 MWe in capacity were in the planning stage.

Total uranium (fuel) requirements of the FRG's nuclear plants for 1977-86 were 33,000 tons, 22,000 tons of which have been secured through supply contracts. In 1978, 65% of the enriched uranium is to come from the United States and 35% from the U.S.S.R. In 1986, 45% is to come from the United States, 35% from URENCO Ltd., a European consortium for enriching uranium, 15% from the U.S.S.R., and 5% from unspecified sources.[7]

Uranium stockpiles in 1977 included 2,000 tons of natural uranium and 2,460 tons of enriched uranium. An agreement concluded in 1977 between Canada and FRG utilities covered 29% of natural uranium requirements for the next decade. In 1977-80, the Republic of South Africa was to supply 4,200 tons of natural uranium, Canada 2,200 tons, France, Gabon, and Niger 1,500 tons, the United States 600 tons, and the others 500 tons.

In 1977, the FRG allocated funds totaling

Digitized by Google

about $1 billion to nuclear energy.

Two FRG companies, helped by Government loans, have sustained an intensive worldwide activity in prospecting for uranium and have secured to a great extent the country's uranium supply. One was Uranerzbergbau GmbH (Bentheim), founded in 1968 by C. Deilmann AG and Rheinische Braunkohlenwerke AG; the other was Urangesellschaft mbH (Frankfurt am Main), founded in 1967 by Metallgesellschaft AG, Steag AG, and VEBA AG.

Prospecting for uranium was in the hands of three companies. Gewerkschaft Brunhilde has operated since 1959 a uranium-processing plant at Ellweiler in Rheinland-Pfalz, producing 50 tons of uranium oxide (U_3O_8) per year from local ores; present ores mined during prospecting at Mezenschwand (Black Forest) are processed at a rate of 150 tons of U_3O_8 per year. Esso-Erz GmbH held uranium concessions in Bavaria, Baden-Württemberg, and Hesse, was prospecting in the Black Forest area, and announced a uranium discovery in the Upper Pfalz. Saarberg-Interplan was prospecting for uranium in Baden-Württemberg, Bavaria, Hesse, Rheinland-Pfalz, and the Saar. In 1975, the company discovered a uranium deposit at Müllenbach in the Murg Valley (Black Forest).

Oil Shale.—Braunschweigische Kohlen Bergwerke planned to build a small-size opencast mine for mining oil shale at Schandelah, located between Braunschweig, Wolfsburg, and Helmstedt, where an estimated 100 million tons of oil is contained in 2 billion tons of shale.

Petroleum and Natural Gas.—There were several important events in the FRG oil and gas industry in 1977.

A new oilfield was found at Neumarkt-St. Veith, 70 kilometers east of Munich. The claim belongs to the Bavarian Minerals Consortium composed of Mobil Oil AG, Gewerkschaft Elwerath, and Preussag AG.

In September 1977, natural gas started to flow from the Norwegian Ekofisk oil and gas fields through a 440-kilometer-long 36-inch pipeline to a gas processing plant, located in Emden on the Ems estuary. The startup of the pipeline was delayed by the approval of the Danish Government, requiring the burying of the pipeline into the sea floor. The Emden gas-processing plant will handle 17 billion to 18 billion cubic meters of North Sea gas per year. Eight billion cubic meters of clean gas are to be delivered to Ruhrgas AG, and the rest will be divided equally among Nederlandse Gasunie (Netherlands), Distrigaz S.A. (Belgium), and Gaz de France.

In 1977, FRG natural gas production increased to 19.5 billion cubic meters, and natural gas imports rose to 31.7 billion cubic meters. Natural gas reserves of the FRG were 185 billion cubic meters.[8]

Deutsche Marathon Petroleum GmbH sold its 40% interest in Erdölraffinerie Mannheim GmbH (ERM) to Wintershall AG, which held the other 60%. ERM owned and operated a 5.6-million-ton-per-year oil refinery in Mannheim.

No commercial oil or gas was found in the FRG sector of the North Sea where the Deutsche Nordseegruppe/BP AG has drilled 40 holes costing $300 million since 1964.

Domestic crude oil production was maintained by the successful use of secondary and tertiary recovery methods as well as extension wells and additional production wells in many oilfields; domestic production supplied only about 4% of domestic demand. Drilling totaled about 242 kilometers in 1977. Proved oil reserves decreased to 42.4 million tons.[9]

With demand stagnating in 1977, the FRG remained Western Europe's largest consumer of crude oil and petroleum products with about 123 million tons of domestic sales.[10]

Imports of crude oil and petroleum products amounted to approximately 139 million tons in 1977. About 78.4 million tons of crude oil including minor quantities of processed oil were imported through five pipelines: Trieste-Ingoldstadt-Karlsruhe (TAL); Wilhelmshaven-Rhine (NWO); Rotterdam-Rhine (RRP); Marseilles-Karlsruhe, Wörth, Speyer-Saarbrücken (SEPL); and Genoa-Ingolstadt (CEL).

Liquid natural gas imports of 8 billion cubic meters per year were the subject of a 20-year contract concluded between a consortium composed of Ruhrgas AG and Salzgitter Ferngas GmbH, both of the FRG; the Nederlandse Gasunie (Netherlands); and the Algerian state company, Sonatrach. Deliveries by Algeria to Wilhelmshaven and Rotterdam (the Netherlands) were to start in 1984.

In 1977, the FRG's petroleum-refining capacity increased slightly owing to an increase by 1.2 million tons at the Saarland Raffinerie GmbH in Völklingen, and minor decreases in the ratings of several other refineries. Yearend capacity (throughput) of FRG refineries is shown in the tabulation following.

The Mineral Industry of Ghana

By T. John Rowland, Jr.[1]

The mineral industry of Ghana in 1977 consisted of the production of bauxite, gold, manganese ore, cement, and diamond. Aluminum, manufactured from imported alumina, and petroleum products, based on imported crude oil, were also included in 1977 mineral production. World and national economic conditions, as well as severe weather conditions that hampered alluvial mining, resulted in decreased bauxite, diamond, gold, and manganese production in 1977. A slight increase was registered in aluminum production from the smelter at Tema.

The Government's 5-year development plan, first presented in 1975, was implemented in 1977 after a series of postponements. The stated objectives of the plan included accelerating the rate of real domestic growth, utilizing more human and natural resources, controlling inflation and the distribution of income, and promoting national economic independence. Total expenditure for the plan was $5.8 billion.[2] The mineral industry was allotted $291 million for expansion and revitalization. About one-third of the cost was to be financed by the Government.

During 1977, Ghana experienced a rapid rise in the rate of inflation. The primary cause was a large Government budget deficit reported at 50% above expenditures. To counteract the situation, various measures were introduced, including relaxation of import controls and initiation of a 20% export bonus on the value of minerals.

The mineral industry remained besieged by rising costs, high taxation, and inadequate transportation facilities inhibiting the shipment of manganese and bauxite ores. Foreign exchange constraints and uncertainty about Government policy toward foreign investors resulted in a decrease in new mining investments.[3] In addition to other economic difficulties, the basic miners wage tripled during the first half of 1977, owing to the imposition of new minimum wage laws.[4]

In the Eastern Region on the Volta River at Kpong, construction of the 160-megawatt Kpong dam and hydroelectric power system began during the second half of 1977. Loans for the $280 million Kpong project were secured from the International Bank for Reconstruction and Development (IBRD), $57 million; the Canadian International Development Agency (CIDA), $35 million; the Kuwaiti Government, $26.7 million; and the Arab Bank for Economic Development in Africa (ABEDA), $10 million.

The Investment Policy Decree of April 1975 was enacted on January 1, 1977. As outlined in the Decree, the mineral industries (except oil and bauxite) were to become 55% Ghanaian if valued above $435,000 and 40% Ghanaian if valued below that level. Government interest in bauxite mining and alumina processing was not to exceed 30%, and its interest in the petroleum industry was not to exceed 20%. Most small commercial and industrial firms were to be completely nationalized.

PRODUCTION AND TRADE

Mineral production as a whole, excluding petroleum refining, decreased in 1977. Individual decreases included bauxite 10%, gold 10%, manganese ore 7%, cement 6%, and

Digitized by Google

diamond 15%. Aluminum metal was the only commodity to register an increase.

Diamond Marketing Corp. (DMC), a Government-owned company, was responsible for marketing Ghana's diamond. DMC held three auctions during 1977 which were open only to firms and individuals registered with DMC. As throughout the past decade, the People's Republic of China bought about 13% of diamond production. The average price at the March sale was $6.50 per carat, an increase of $1.30 over the corresponding 1976 price.[5]

Despite the decrease in production, the value of gold produced in 1977 increased nearly 8% over that of 1976. As the most valuable Ghanaian mineral commodity, gold accounted for $94.6 million in exports.[6]

The Ghana Supply Commission remained the only importer of petroleum and the chief exporter of petroleum products. Crude petroleum was imported primarily from Nigeria, with lesser amounts from Libya and the U.S.S.R. Ghana's annual oil cost has risen steeply in recent years to $150 million, which has intensified the country's search for domestic sources of petroleum.[7]

Table 1.—Ghana: Production of mineral commodities

Commodity[1] and unit of measure	1975	1976	1977[p]
METALS			
Aluminum:			
Bauxite, gross weight ---- metric tons	319,526	271,563	244,217

Residual fuel oil ---- do	2,811	2,440	2,589
Other ---- do	--	98	92
Refinery fuel and losses ---- do	445	466	384
Total ---- do	9,118	8,493	8,663

[e]Estimate. [p]Preliminary. [r]Revised.

[1]In addition to the commodities listed, a variety of crude construction materials (clays, sand and gravel, and stone) are also produced, but output is not reported and available information is inadequate to make reliable estimates of output levels.

COMMODITY REVIEW

METALS

Aluminum.—Bauxite deposits, accounting for 2.5% of total world reserves, were located in the areas of Nyinahin, Awaso, and Kibi. Reserves at the Nyinahin deposit, located in central Ghana, were estimated at 580 million tons of ore. In western Ghana, reserves of 20 million tons of ore were estimated at the Awaso deposit. The Kibi bauxite deposit, located approximately 80 kilometers from the coast, had reserves of 182 million tons of ore.[8]

The feasibility of development of the large Nyinahin bauxite deposit was studied by Chemokomplex/Aluteru of Hungary, with the objective of establishing a fully integrated aluminum industry in the area. Additionally, Chemokomplex was to appraise the feasibility study conducted by Bauxite and Alumina Study Co. Ltd. (BASCOL), a dissolved consortium, on construction of an alumina refinery in the Kibi region. The 600,000-ton-per-year alumina plant was to begin production in the 1980's.

Ghana Bauxite Co. Ltd. (GBC) operated Ghana's only bauxite mine at Awaso. The 500,000-ton-per-year mine was jointly owned by the Government 55% and British Aluminium Co. Ltd. 45%. In 1977, Ghana

Digitized by Google

possessed three of the five stages of aluminum production—mining, smelting, and fabrication—but did not yet produce alumina or have a rolling mill. Problems associated with insufficient railroad facilities from Awaso to the port at Takoradi continued to hinder production throughout the year.

Volta Aluminum Co. Ltd. (VALCO), owned by Kaiser Aluminum & Chemical Corp. 90% and Reynolds Metals Co. 10%, operated a 198,000-ton-per-year aluminum smelter at Tema. The smelter produced 153,000 tons of aluminum ingots from imported alumina in 1977. In early July, a nationwide power failure closed three of the five smelter potlines. The power failure was apparently owing to an overload on the Akosombo hydroelectric system. Three months were required to repair the damaged potlines and resume operations.[9]

A consortium led by Mitsubishi Metal Corp. of Japan was conducting a feasibility study for a second smelter of 200,000- to 300,000-ton-per-year capacity at Tema. A tentative agreement was reached between Hunter Engineering Co. of the United States and the Government to establish and operate a casting, rolling, and finishing plant at Tema, which was expected to process the VALCO aluminum ingots.

Gold.—Ashanti Goldfields Corp. (Ghana) Ltd., owned by State Gold Mining Corp. (GMC) 55% and Lonrho Ltd. of the United Kingdom 45%, operated a 259-square-kilometer concession in the Bakwai and Obuasi districts of the Ashanti Region. The mine extended over 16,000 feet along the strike of the ore body, with seven main surface shafts and three main internal shafts. Gold reserves in 1976 were estimated at over 3.6 million tons of ore with an average grade of 24 grams per ton. In 1977, the mine produced 340,229 troy ounces of gold. The company announced plans for construction of a new shaft at a cost of $3.3 million. Upon completion of the shaft in 4 years, the effective working depth of the mine is expected to be increased by 1,000 feet at each stage.

Dunkwa Goldfields Ltd., a subsidiary of GMC, ceased production early in the year because the alluvial dredges ordered in 1975 were not ready for delivery, although they were near completion. Gold reserves for the alluvial mine were estimated at 327 million cubic yards of ore. Tarkwa Goldfields Ltd. and Prestea Goldfields Ltd., subsidiaries of GMC, produced 56,269 troy ounces and 79,649 troy ounces of gold, respectively.[10]

The Government initiated feasibility studies for reopening the abandoned mines at Akrokerri, Maupambue, and Obenemasi. Prospecting and dredging operations for alluvial gold were to be intensified by GMC along the banks of the Bonte, Fure, and Bonsu Rivers.

Iron and Steel.—Construction of a $522 million iron and steel complex near Sekondi was started by the Government with technical assistance provided by Fried. Krupp GmbH (Federal Republic of Germany). The new complex was designed with a capacity of 200,000 tons per year of iron ore. The estimated 30-million-ton iron ore reserves at Wuwuoso, north of Tarkwa in the Opon Mansi area, were to be exploited by open pit methods to supply the complex.[11]

Manganese.—The Nsuta manganese mine in western Ghana was operated by Government-owned Ghana National Manganese Corp. (GNMC). Since 1974, GNMC has purchased all manganese ore mined in Ghana, with Caemi International of the Netherlands serving as marketing agent. Manganese ore production decreased 6.5% in 1977. The open pit mine produced both high-grade manganese dioxide (40% to 47% manganese) and lower grade manganese carbonate (30% manganese) ores. Manganese dioxide production diminished because of ore depletion. GNMC planned construction of a concentrator for beneficiating the manganese carbonate ore.[12]

GNMC was to reevaluate the reserves and conduct a feasibility study for development of manganese carbonate ore. The ore was transported from the Nsuta mine to the port of Takorodi for export to 11 countries.[13]

NONMETALS

Clays.—A $6.9 million brick and tile factory at Prampram was expected to be completed and begin production in late 1977. The factory, built to meet the building requirements of the Greater Accra Region, was designed with an annual production capacity of 36 million tons of brick and tile.

Diamond.—Ghana Consolidated Diamonds Ltd. (GCDL) controlled 99% of 1977 diamond production. GCDL was jointly owned by the Government 55% and Consolidated African Selection Trust Ltd. (CAST) of the United Kingdom 45%. Approximately 90% to 95% of the diamond recovered was industrial quality. Production from GCDL mines at Akwatia in eastern Ghana was 1,946,587 carats. Reserves of the Ak-

Digitized by Google

watia deposit were estimated at 11.5 million carats and were expected to be depleted in 5 years. GCDL began development of an area near the confluence of the Pra and Birim Rivers. The 64-square-kilometer area, with estimated reserves of 50 million carats, was to be mined at a rate of 2 million carats per year.[14]

MINERAL FUELS

Petroleum.—In 1977, Agri-Petco Inc. of Tulsa, Okla., discovered oil 9 miles off the coast near Saltpond in the Central Region. The three 9,000-foot wells drilled by the company in the Bonsu field were each rated at a minimum of 1,000 barrels per day of sulfur-free, 36° to 39° API gravity crude oil.

The Government granted prospecting licenses to Oxoco International (United States) and Aracca Petroleum for two offshore areas totaling 3,240 square kilometers. Offshore Hydrocarbons (United States) obtained exploration rights to 4,890 square kilometers of the Ghanaian continental shelf. The U.S. Government firm Overseas Private Investment Corp. agreed to insure oil company interests against political risks. Private investments in Ghanaian offshore oil exploration were reported at $35 million.[15]

Phillips Petroleum Co. relinquished the rights to 5,200 square kilometers of onshore and offshore concessions, and Oxoco surrendered a 3,440-square-kilometer offshore concession.

Shell Oil Co. abandoned the search for onshore oil in the Voltarian Basin of the Brong-Ahafo Region. Although promising petroleum findings were not reported, the geological knowledge of eastern Ghana was significantly expanded.

The Mineral Industry of Greece[1]

By Roman V. Sondermayer[2]

The mineral sector of the Greek economy, including processing, contributed about 6% to the country's gross national product (GNP) in 1977. The share of the mining and quarrying sector was only 1.3% of the total GNP. The growth of the mineral industry production index was higher than that of the rest of the economy because of strong government involvement in the mineral industry. The mineral industry employed an estimated 19,000 persons, or 0.6% of the total labor force.

Bauxite and the nonmetals were the most important minerals produced in Greece during 1977. Greek production of bauxite, magnesite, barite, perlite, and nickel was between 1% and 3% of world production. Output of other minerals was of only domestic significance.

During 1977, large government-sponsored mineral projects were underway, and the Government retained a major role in development of mineral wealth and the mineral industry through its own agencies and through government-controlled companies. Participation of foreign partners was welcome, but the foreign share in joint ventures was held under 50%.

In August 1978, Parliament passed Law No. 669 regulating the exploitation of quarries. This law requires use of modern methods of production and contains very strict provisions for safeguarding the environment.

During 1977, major events in the mineral industry were expansion of the capacity of bauxite mines at Parnassos-Ghiona in central Greece; modernization of the chromite beneficiation plant at Skoumtsa; closing of lead mines at Laurium; expansion of nickel-producing facilities at Euboea; beginning of construction of a 350,000-ton-per-year bentonite plant on Milos Island; and expansion of lignite mines at Megalópolis, Amynteon, and Ptolemais.

PRODUCTION

The mineral industry was privately owned, but the Government increased its activities in the field of mining and processing minerals through its own organizations, mostly publicly owned corporations. The principal ones were Public Power Corp. (PPC), the Public Petroleum Enterprise (DEP), Hellenic Industrial & Mining Investment Co. S.A. (HIMIC), Project Studies & Mining Development Corp. (GEMEE), and Geological and Mining Research Institute Activity (IGME). In addition, the Government was pushing ahead large investments using its own financial institutions such as the Hellenic Industrial Development Bank (ETVA).

The following tabulation shows major companies operating in Greece during 1977:

TRADE

Greece had a negative trade balance in minerals during 1977, largely owing to imports of fuels, which accounted for about one-third of the country's mineral imports. Tables 2 and 3 show trade statistics for selected commodities. The United States had an active trade balance in minerals with Greece. U.S. exports of minerals to Greece were valued at about $55.4 million, and coal and iron and steel products were the major items. U.S. imports of minerals from Greece were valued at about $27.2 million, and major items were residual fuel oils and clays. Table 4 shows details.

COMMODITY REVIEW

METALS

Aluminum.—Greece remained an important producer and exporter of bauxite and was more than self-sufficient in output of alumina and aluminum.

Bauxite.—Bauxite Parnasse Mining Co. S.A. (BPM), owned by the Eliopoulou-Kyriacopoulou Group, remained the leading bauxite producer and exporter in Greece. At its Parnassos-Ghiona mines in central Greece, work continued on expanding capacity from 2 to 3.5 million tons per year. The program included increasing capacity of underground mines from about 500,000 tons to 1.5 million tons per year by 1982.

Eleusis Bauxite Mines (Scalistiris Group), second largest producer of bauxite in Greece, with mines in Eleusis, Lamia, Itea, and Kyria, continued building two 250,000-ton-per-year heavy-media separation installations for processing high-lime bauxite and tailings at Eleusis and Lamia. Completion has been scheduled for 1978. During 1977, Eleusis Bauxite Mines produced about 720,000 tons of bauxite.

Elikon-Bauxite-G. Barlos S.A. (Elikon) was expanding its capacity for bauxite production to 400,000 tons by 1978. During 1977, Elikon produced about 280,000 tons. During 1977, Nucleonic Hellas conducted exploration for bauxite near Vronteron and Florina, northern Greece. Preliminary results indicated existence of an important deposit of alumina in the form of gibbsite.

Alumina and Aluminum.—During 1977, Aluminium de Grèce (AG), partly owned by Pechiney of France and the only alumina and aluminum producer in Greece, was preparing plans for capacity expansion of its alumina plant at Distomon, Boeotia, by 100,000 tons per year to 600,000 tons. Plans indicated a total investment of about $100 million, including about $40 million for foreign-made equipment. The entire additional alumina output will be exported.

BPM continued efforts to find foreign

Digitized by Google

partners for investment in a new 600,000-ton-per-year alumina plant at Itea on the Corinthian Gulf. This investment was approved by the Greek Government in 1976, and HIMIC is the cosponsor of the project. Chemokomplex and Aluterv of Hungary, which will provide "know-how" for the plant, revised their figures on investment and production costs during 1977. Based on the new figures further discussions with possible foreign partners were scheduled for 1978. Foreign participation cannot exceed 49%.

Chromite.—The Greek Government, through IGME and GEMEE, continued efforts to determine chromite reserves (previously estimated at 2 million tons) at Vourinos Mountain near Kozáni. At Skoumtsa mine, GEMEE was modernizing outdated mining equipment and beneficiation facilities. After completion of the program, capacity for production of 50% to 52% Cr_2O_3 chromite concentrate should increase from 15,000 tons per year to 60,000 tons per year.

The Government was, in addition, examining the feasibility of establishing a ferrochrome industry in Greece. The Finnish firm Outokumpu Oy completed a feasibility study, but at yearend no decision had been made.

Iron and Steel.—After several months of trial operation, a new 260,000-ton-per-year steel miniplant started normal production. The plant is located in the Almiros area near Vólos.

The only integrated steel producer in the country remained Halivourgiki Inc., with a plant near Eleusis, based on imported iron ore and coke which accounted for about 60% of the country's steel production. Shipbuilding remained the principal consumer of domestic and imported steel and steel products.

Lead, Zinc, Pyrite, Copper.—Production of complex sulfide ores containing lead, zinc, copper, and pyrite was down 30% when compared with output in 1976 because of a strike and closure of the mines.

During 1977, a 7-month-long miners' strike closed the Kassandra mines; the beneficiation plant at Stratoni; and Olimpias mines and beneficiation facilities operated by the Hellenic Chemical Products & Fertilizers Co. Ltd. (HCPF), Bodossakis Group. HCPF was also closing its Hermoni copper-iron-pyrite mine, southeast of the city of Nafplion, Peloponnesus, because of economics and pollution problems. To compensate for the impact of closing the Hermoni mine, the company started developing marble reserves in the area.

After 100 years of operation, the Cie. Francaise des Mines du Laurium closed down its mines at Laurium. Low lead content of ores and low lead prices on the international market made operation at Laurium uneconomic.

Nickel.—Larco Co. S.A. (Bodossakis Group) continued expansion of its facilities at Euboea and Boeotia from the present 15,000 tons to 27,000 tons of nickel, reportedly to be completed during 1978. During 1977, construction began on a 10-kilometer conveyor belt from the opencast mines to the crushing facilities at Politika in northwest Euboea. About 80% of the equipment needed for expansion was delivered, including a rotary kiln from Krupp, Federal Republic of Germany, and two electrofurnaces and other equipment from France. Because of technological improvements and escalating pollution control costs, the Greek Government has approved Larco's request to increase the original investment of $50 million to $68 million.

Eleusis Bauxite Mines was awaiting Government approval to invest $60 million to $65 million in a new 10,000-ton-per-year nickel plant on Euboea; consequently all major work remained at a standstill through the year. The project also includes development of a 70-million-ton deposit of lateritic ore, with an aggregated average metal content of nickel and cobalt of 1%, located at Pashna, Euboea. Bechtel Corp. of the United States was to provide engineering and construction management. Elkem-Spigerverket A/S of Norway was to act as consultant.

NONMETALS

Asbestos.—The Greek Government has decided to go it alone on development, through ETVA, of the Zidanion mines near Kozáni. ETVA organized a company named Asbestos Mines of Northern Greece. Mining Sociètè Anonyme (AMNG) and the new company started operation at Zindanion mines at Kozáni. As a result of activities during 1977, asbestos reserves at Zidanion were revised upward to 90 million tons.

In November 1977, AMNG applied to the authorities for approval of a $68 million investment to build, by 1980, a 100,000-ton-per-year asbestos fiber plant at the Zidanion asbestos mine near Kozáni; the plant would employ 300 persons, and about 75% of its fiber output would be exported. U.S.

Digitized by Google

standards of pollution control will be applied. Killburn Engineering Ltd. of Toronto, Canada, was appointed technical advisor for the project.

Barite.—Mykobar Mining Co. S.A., the major barite producer in Greece, a subsidiary of Dresser Industries of the United States, was examining possibilities for bringing into production additional barite reserves on Mykonos Island. During recent exploration activities, geologists from Mykobar proved existence of a new 400,000-ton barite deposit on Mykonos. Preliminary results of exploration near the shore of the island indicated an additional 1.2 million tons of barite under the sea.

Nearly all of the barite produced in the country was exported to the United States and other oil producing countries.

Bentonite.—The Silver and Baryte Ores Mining Co., a major producer of bentonite and other industrial minerals in Greece, started construction of a 350,000-ton-per-year bentonite processing installation on Milos. During 1977, the company completed about 50% of the project, including a drying plant. Plans called for completion of the project by 1979.

Cement.—During 1977, the Titan Cement Co. S.A. (Titan) obtained Government approval to spend about $44 million for construction of a 1-million-ton-per-year cement plant at Kamari, Boeotia. Titan expects to complete this project by 1981. In addition, modernization of the Aspropyrgos plant in Attica, operated by Halyps Cement Co. S.A., continued during 1977. A French-German-made rotary kiln and associated equipment will replace three obsolete cement kilns, and the Aspropyrgos plant capacity should increase from 450,000 tons of cement per year to 600,000 tons per year by 1979. The management of Halyps estimated an expenditure of about $1.6 million for pollution control equipment for the Aspropyrgos plant.

During 1977, the cement industry in Greece produced almost at full capacity of 11.7 million tons per year. Four companies operated eight plants; Heracles General Cement Co. S.A. and Titan were the largest operators, accounting for 36% and 35%, respectively, of installed cement capacity in Greece. The largest cement plant in Greece was Olympos at Volos, with a capacity of 3 million tons per year, operated by Heracles General Cement Co. S.A. About 53% of total cement output in Greece was sold on the domestic market.

Magnesite.—During 1977, the magnesite industry of Greece was hit hard by the steel recession in Europe, and uncertainties about the future of the national economies of Western Europe resulted in delaying planned expansion in the magnesite industry.

Financial Mining-Industrial and Shipping Corp. (FIMISCO), the largest producer of magnesite, temporarily halted development of a $50 million plant for producing refractory magnesia from seawater and dolomite. In addition, the company canceled plans to develop magnesite mines on Levbos Island.

Macedonian Magnesite Mining Industrial and Shipping Corp. postponed implementation of a plan to build a plant for production of briquetted dead-burned magnesite at the firm's mining site at Ormelia, Chalkidiki.

Although Grecian Magnesits Ltd. S.A. purchased some mining equipment for its open pit mines at Gerakini, Chalkidiki, it postponed purchase and installation of a third 160 to 180-ton-per-day-capacity rotary kiln for its sintering facilities. Magnomine General Mining Co. S.A., a subsidiary of General Refractories (United States), delayed purchase of a new 250-ton-per-day shaft kiln for its magnesite-processing installations at Chalkidiki.

Marble.—GEMEE started marble production from a quarry at Verria in northern Greece, and plans were underway to start another quarry in the Attica region. Planned aggregated annual output of both quarries was set at 8,500 cubic meters of marble.

The Hellenic Chemical Products and Fertilizers Co. started development of marble production at Hermoni, near Nafplion, Peloponnesus. The size of the operation was not made public.

Quartzite.—Forty kilometers northeast of Thessaloniki, Hellenic Industrial Minerals S.A. (Elvior) started production from a new quartzite quarry. Reportedly the quartzite is of 99% purity and is suitable for production of metallic silicon. Reserves were not reported. Planning for expansion of the mine and construction of a mill was underway at yearend. The product will be exported to countries in Western Europe.

MINERAL FUELS

Imported petroleum remained the principal source of energy in Greece. During 1976, the last year for which complete data were available, about 83% of Greece's apparent fuel and power consumption was met

Digitized by Google

through imports. Petroleum and refinery products accounted for approximately 97% of primary energy imports. Lignite was the principal source of energy produced in the country and provided 26% of apparent energy consumption. However, additional imports of high-rank coals were necessary to meet demand. Table 5 shows supply and apparent consumption of fuel and power for 1975 and 1976 in million tons of standard coal equivalent (SCE).

Table 5.—Greece: Supply and apparent consumption of fuels and power

(Million tons of standard coal equivalent)[1]

Coal.—Lignite was the only mineral fuel produced in significant commercial quantities in Greece during 1977. High prices for imported energy made domestic low-grade lignite, neglected in the past, an important source of energy. IGME conducted exploration for lignite, mostly in northwest Greece, with funds supplied by the Government-owned PPC, the major lignite mine operator in the country. PPC also was involved in expanding operational lignite mines.

Out of total production of 23.2 million tons of lignite, 16.1 million tons were produced from the Ptolemais mines, 6.7 million tons were mined at the Megalópolis lignite field, and the rest came from mines at Aliveri, Euboea. Most of the lignite produced was used for production of electric power. Lignite-fired powerplants accounted for about 60% of the total electric energy produced in the country.

The search for lignite was intensified during 1977. Exploration drilling totaled 15,799 meters. Exploration was concentrated in the areas of Amynteon, Valtonora near Amynteon, Xyrolimni near Kozáni, Elos in Edhessa, and Perdika Komninan. Preliminary results indicated a 200-million-ton lignite deposit. Amynteon was the site of the most intensive exploration. During 1977, as a result of exploration, measured reserves at Amynteon were increased from 140 million tons to 225 million tons. Plans were announced to develop a mine, and a preliminary engineering study should be completed by the end of 1978. Lignite from Amynteon was planned for use in each of two 300-megawatt units, scheduled to start production in 1985 or 1986.

Most mine expansion activities were conducted by PPC in the lignite fields of northern Greece. At the Ptolemais mines, operated by PPC, measured lignite reserves were increased from 1.4 billion tons to 2.1 billion tons as a result of additional exploration. In the same area, the development of Ptolemais' untapped South field was stepped up during 1977. A Federal Republic of Germany firm, Otto Gold GmbH, completed an engineering study for PPC to develop South field to supply seven additional 300-megawatt-power units at Kardia. In November 1977, PPC signed a contract with a Greek firm, Metal Construction of Greece S.A. (METKA), for construction and installation by 1980 of a 12-kilometer conveyor belt for moving overburden in the South field. A second conveyor belt system was planned to move lignite. Planned production in the South field was between 16 and 18 million tons per year in 1980 and between 40 and 42 million tons per year by 1990.

At the PPC-operated Megalopolis mine, Greece's second largest lignite producer,

Digitized by Google

preparation continued to increase output to 14 million tons by 1990. During 1977, the Federal Republic of Germany's consultant, Hanz Goergen, completed an engineering study for development of the Kilparissiom and South Horemi fields at Megalópolis. Tenders for purchasing mining equipment (five bucket wheel excavators, two stackers, one walking-type dragline, etc.) were to be issued during 1978.

The Aliveri lignite deposits are approaching exhaustion, and PPC intends to close the mines between 1980-82. In addition to domestic lignite, Greece imported high-rank coals and coke to meet its industrial demand. Tables 2, 3, and 4 show foreign trade of Greece in coal and coke.

Petroleum and Natural Gas.—During 1977, Greece remained without domestic crude oil and natural gas production, and all the country's demand was met through imports. However, preparation for development of a recently discovered offshore deposit and offshore and onshore exploration for crude oil and natural gas were underway.

Exploration.—Most of the offshore exploration was carried out near the island of Thássos and most of the onshore exploration was in the nearby delta of the Nestos River in northern Greece. Exploration activities offshore consisted of geophysical work and drilling in the area called South Thássos. The North Aegean Petroleum Corp. operators for Denison Consortium, made arrangements for the drilling ship, *Wodeco,* to drill three exploratory wells in the Thássos area during 1978. Under the contract between the Government and Denison, exploration in the Thássos area was to be completed within the 1978-79 period.

DEP specialists, together with consultants from the French Institut Français du Pétrole, evaluated results of drilling the Nestos I and Nestos II wells in the Nestos Delta, which were completed by contractors from Romania. To determine the site of the Nestos III well, additional seismic work was done by Rogers Exploration Co. of Houston. By yearend, Romanian contractors for Nestos III had completed drilling to a final depth of 3,500 meters. In addition, a well in the Komotini area was completed at 2,500 meters. Results of these two drillings were not made public at yearend.

Furthermore, as a result of contracts signed by DEP, the U.S. firm Geophysical Service, Inc., and the French firm Cie. General de Geophysique, exploration commenced in the areas of the Ionian Sea; Préveza; and the Corinthiakos, Patriakos and Kyparissiakos Gulfs. In addition, DEP completed a survey of the Xanthi-Komotini area in western Thrace and DEP was also conducting exploration in the Philippoi Plain, near Kaválla, and stratigraphic surveying in the Strymon River valley, Serres area.

Production.—During 1977, preparations were underway to start development of the Thassos oilfield, the first oilfield in Greece, for a target output of 25,000 barrels of oil per day. Some problems related to location of the production platform must be resolved before actual work can start.

Refining.—During 1977, four petroleum refineries, with annual capacity of 20 million tons, were in operation in Greece. The largest refinery was Motor Oil (Hellas) Corinth Refineries, Corinth, with an annual capacity of 7 million tons of crude oil.

Uranium.—The United Nations Development Program's assistance in training Greek personnel ceased in September 1977. Scientists from Democritus Research Center continued exploration for uranium in eastern Macedonia and Thrace. Preliminary results were encouraging.

The Mineral Industry of Hungary

By George Rabchevsky[1]

In 1977, Hungary's national income was 474 billion forints (Ft),[2] 46% of which came from industrial operations, 16% from agriculture, 16% from transportation and telecommunications, 8% from commerce, and 14% from water management. According to the 1977 budget, revenues totaled Ft361 billion against total expenditures of Ft365 billion, thus showing a deficit of Ft4 billion. The mining industry contributed Ft10 billion to Hungary's total revenues (Ft361 billion) in 1977, and the metallurgic industry accounted for Ft8 billion of the total, representing 10% and 8% of total heavy industry revenues (Ft104 billion) in 1977, respectively. The contribution of the minerals sector to the overall economy in 1977 is given in percentages in the following tabulation.

Industry	Gross production	Total employment
Mining	3.9	7.0
Metallurgy	9.7	5.9
Iron and steel manufacturing	2.9	3.8

Sources: Statisztikai Evkönyv 1977 (Statistical Yearbook 1977), Budapest, 1978. Statistical Pocket Book of Hungary 1978, Budapest, 1978.

Geologic maps show that, in general, most of the mineral resources of Hungary occur along definite structural zones and are confined to a narrow band of highlands and foothills, extending in an arc-like fashion across the country from southwest to northeast. The natural resources of Hungary are primarily of sedimentary origin and only a few are magmatic. Hungary produces some 70 different mineral commodities. In comparison to its neighboring countries, Czechoslovakia, Austria, Yugoslavia, and Bulgaria, Hungary may be considered in the mid-field in regard to mineral self-sufficiency. Almost 50% of its mineral requirements can be supplied from domestic sources.

Worldwide, Hungary occupies a leading position in bauxite reserves and production, even though mining there began later than in other European countries (about 50 years ago). Hungarian oil exploration began just before World War II. Systematic geologic exploration has led to the discovery of large reserves of bauxite and of less abundant reserves of oil, natural gas, and manganese ore. However, with the exception of bauxite and manganese ore, there are insufficient supplies of metallic ores.

Iron ore deposits are located in the northeastern uplands near Miskolc. Rudabánya, the largest open pit mine, is the principal source of iron ore, with an annual production total of 400,000 tons. Manganese is mined mostly at Urkút and Eplény in the Bakony Mountains, north of Lake Balaton. This oxidized and partly carbonaceous manganese ore occurs in marine Jurassic deposits.

Uranium was discovered in Hungary in 1954 near Pécs in the Mecsek Mountains and there probably are also deposits along the Száva River near the Czechoslovakia frontier. The concentrated uranium ore localities are associated with the weathering of the Paleozoic granites and Paleozoic-early-Mesozoic (Permian) sandstones. Little is known, however, about these apparently rich deposits except that ore from them is exported to the U.S.S.R. for processing.

Most of Hungary's coal deposits are found in the foothills of the main uplands, cross-

Digitized by Google

ing the country in a southwest-northeast direction and in the Mecsek Mountains. The largest lignite basin in Hungary is at Borsod, where coal occurs in Upper Tertiary deposits of the Sajó Valley, east of the Danube. West of the Danube, lignite is found in a basin between Tatabánya and Ajka Valleys and at Szombathely. Bituminous coal is mined at the foothills of the Mecsek highlands, near the towns of Pécs and Komló, in the southwestern part of the country. Hungary provides most of its own coal and natural gas requirements and exports bauxite. Most of its raw materials come from the U.S.S.R. and it imports the more advanced types of capital goods and certain raw materials from the West.

Government Policies and Programs.—Hungary enjoyed strong economic growth in 1977. However, this strong domestic performance was marred by a growing trade deficit. Imports in 1977 increased sharply (18%), spurred by above-plan investments and higher prices; exports were 10% lower than imports, owing to unfavorable external conditions, the high level of domestic demand, and the continuing noncompetitiveness of many Hungarian products in world markets. Among the Eastern Europe centrally planned economies, Hungary ranks behind the German Democratic Republic and Czechoslovakia statistically in per capita income. However, under economic reform and other measures introduced officially in 1968, which encouraged enterprise initiative and flexibility, the quality of life and relative availability of consumer goods have improved greatly.

Since Hungary started its first 5-year plan in 1956 (1956-60), it has completed four such plans and is now in its fifth 5-year plan (1976-80). The 1977 plan had posted as a goal a strong improvement in economic efficiency over that of the 1976 year, so as to accelerate growth in the national income and to approach the prescribed expectations of the 5-year plan. The national income increased in 1977 by 10%, exceeding the projected 7% and reaching Ft474 billion. At the same time, the consumer price level, wages, and income also increased much more than planned for 1977. Also, domestic consumption, projected at 4%, increased by 5%.[3]

Capital investments, at Ft201 billion, exceeded the 5-year plan by 10%, resulting in an unbalanced economy. Record high investments in the development of the copper mine at Recsk and the implementation of the Eocene mining program probably contributed significantly to the 1977 budget deficit. Thus, one of the goals of the 1978 plan is to improve production efficiency and the economic balance.

Hungary's foreign trade increased dynamically in 1977 and the 1978 goal is the further expansion of the financial resources for export oriented developments. The value of foreign trade increased by 18% in 1977 to Ft503 billion. A bank office that opened in New York in 1977 is also expected to contribute to the expansion of Hungarian-American economic contacts.[4]

In comparison, industrial production in 1977 increased 7% making up for the 1976 lag in output. However, the external and internal economic balance still deteriorated and was at variance with the 1977 planned target. While exports to centrally planned economy countries increased 19% during 1977, exports to market-economy countries lagged (at 9%) behind the planned targets, and imports from the latter were greater (by 19%) than planned.[5]

The fifth 5-year plan (1976-80) calls for a total investment of Ft870 billion in development of the national economy, about 25% more than in the previous 5-year period. The plan outlines a number of investment priorities. For example, it prescribes that electric power generating facilities be increased 1,500 megawatts; the Danube (Duna) Vasmü steel and coking plant is to be expanded and modernized; the Szekesfehervar Könnyüfemmü (light metal) plant is to be expanded; and refining facilities for olefin production are to be developed. The plan also calls for significant investments to be made in the Borsodi Vegyi chemical complex, the Tiszai Vegyi complex (partly for the production of fertilizers), and the Belapatfalva cement plant. The majority of these projects have been proceeding as planned. Many of them have been finished and some are already in the production stage; however, there are also backlogs. Construction of electric power facilities and the Danube Vasmü coking plant is lagging.

Digitized by Google

Also, completion of the Bélapátfalva cement plant and the construction of the Borsod chemical complex (No. 4 nitrogen plant) have been delayed by a year. The 1977 national economic plan envisaged completion of 14 major construction projects, some of which were backlogs. At yearend, production equipment was already in operation in six projects and only the finishing touches were required: The second stage of the Danube oil refinery, the second and third stages of the Danuamenti thermal power station, the cement plant at Hejöcsaba, and the nitrogen and asbestos cement works at Nyergesújfalu. The basic capacities have also been put into operation in the first and second stages of the Hungarian-Soviet gas pipeline. The installation of the telecommunications system of the pipeline was to be left until the beginning of 1978.

At the Almásfüzitö alumina plant, the annual alumina production capacity was increased by 40,000 tons or 5% in 1977, and output at the Nyirád-Deák bauxite mine, by 350,000 tons. The capacity of the Tisza thermal powerplant was expanded by almost 430 megawatts, or 10%. At the Ózd metallurgical works, a new steel production unit was placed into operation.[6]

Special attention is to be focused on the metallurgical sector in the fifth 5-year plan. Renovation of the various ironworks and the development of ferromanganese production are to be made, and maintenance and management of the steelworks are to be improved.[7]

The 1978 plan envisages production of coal to be 25 million tons; petroleum production, 2 million tons; and natural gas extraction, 247 billion cubic feet. Some of Hungary's energy resources are to be imported from the Council for Mutual Economic Assistance (CMEA)[8] countries, primarily from U.S.S.R.

In 1980, the share of petroleum and natural gas in total energy consumption is expected to be 62%; coal is expected to supply 32%; and hydroelectric and imported power, 6%. During the fifth 5-year plan, Hungary is to devote 15% of its total investments to the development of the energy sector.

In 1977, the construction of two new lignite coal mines, with a designed capacity of 4 million tons each, was underway in the Transdanubia region. Despite increased production of domestic energy, the Hungarian economy's dependence on imports continued to grow. A 750-kilovolt electric transmission line between Vinnitsa (U.S.S.R.) and Alberti is to be completed by the end of 1978, and more are to be strung later. Also, nearing completion were the "Szovetség"-Orenburg natural gas pipeline (a CMEA project) and the Adriatic petroleum pipeline (a Hungary-Yugoslavia-Czechoslovakia project). The first stage of the 1,760-megawatt nuclear power station at Paks was under construction and more are being planned. Hungary does not have a totally independent electric power system and receives much of its power from CMEA countries; as a member of a nearly 83,000-megawatt electric energy cooperative, it receives and shares electric energy with Bulgaria, Romania, Czechoslovakia, Poland, the German Democratic Republic, and the west Ukraine of the U.S.S.R.[9]

PRODUCTION

The actual growth rates of industrial production in Hungary during the last three 5-year plans were 7.5% in 1961-65 (second), 6.2% in 1966-70 (third), and 6.4% in 1971-75 (fourth). The planned industrial growth rate during the current 5-year plan (1976-80) is 6% and the change in 1977 was 6.6% over that in 1976.[10] Although Hungary has a poor raw materials base, the leadership has recognized the country's historical strength as an agricultural supplier and has provided capital and encouragement to develop this sector. However, Hungary has a chronic labor shortage, so that economic progress must come almost entirely from increased labor productivity. In the recent past, Western economic uncertainties and deteriorating terms of trade with both the West and the U.S.S.R. (principal supplier of most raw materials) have caused serious difficulties.

The contribution by industry to the Hungarian national income increased from 36.6% in 1960 to 46.3% in 1976 and decreased to 46% in 1977. The anticipated 1978 output is to increase by almost 7%. As part of this planned increase, a new plant at the Borsod chemical complex and the plant at

Digitized by Google

the Tizsa chemical combine are to begin production in 1978. More synthetic materials are to be imported from the centrally planned economy countries and the production and purchase of natural gas, oil, iron and steel, and other mineral commodities are to be increased.

Efforts were made to improve industrial production by dropping uneconomic products and continuing to increase specialization. Industries identified for rapid development in the 5-year plan included aluminum, machine tools, food processing equipment, pharmaceuticals, buses, and vehicle parts. The Government also allocated investment funds to increase exploitation of Hungary's modest oil and natural gas resources and to expand coal production, in order to reduce dependence on energy imports.

Production of many metallic minerals remained almost unchanged in 1977. This stabilization was noticed in bauxite, iron ore, lead, and zinc. In contrast, the production of some nonmetallic minerals showed a considerable increase to about 1 million tons (almost four times that of 1967). The volume of limestone production doubled.[11]

The production and sales volume of the metallurgical industry in 1977 exceeded the 1976 level. This expansion of domestic production made it possible to meet the increased obligations to the centrally planned economy countries and to broaden the export product base to the market-economy countries. In 1977, the gross production value of manufactured metals at current prices was Ft65 billion. This amount exceeded the 1976 base by Ft3 billion or 4.5%. The 1976-77 production values for some of the metallurgical products are shown in the following tabulation in billion forints:

	Production values		
	1976	1977	Index (percent)
Ferrous	44.3	45.9	103.6
Aluminum	12.5	13.6	108.8
Nonferrous	5.7	5.8	101.8
Total	62.5	65.3	104.5

Source: Kohászat (Metallurgy), Budapest. V. 3, No. 8, 1978, pp. 366-370.

The 1977 profit of the metallurgical industry was Ft5 billion, which represents a 2% decrease from that of the preceding year (mostly in the ferrous metallurgical industry). The overall 1976-77 sales and production values of the metallurgical industry are shown in the following tabulation in million forints:

	1976	1977	Index (percent)
Production values	62,479	65,300	104.5
Sales values	61,566	65,116	105.8

As can be seen from the tabulation, in 1977 the increase in earnings surpassed that of production. Domestic sales of metal products in 1977 exceeded those for 1976 by 3.6% or Ft1.6 billion. Domestic sales of ferrous products increased 5.8% or Ft1.9 billion, while the demand for aluminum products decreased slightly, and earnings were 0.3% or Ft200 million less.

The mining industry employed 119,000 individuals in 1977, but planned mechanization is expected to reduce this number to 100,000 by 1990, while productivity is to increase 25%. The metallurgical industry employed 100,000 individuals. The 1961-77 statistics for accidents in the mining and metallurgical industries are given in the following tabulation:

Industry	Reported accidents	Fatal accidents	Accidents per 1,000 workers
Mining	8,567	28	87.5
Metallurgical	3,933	10	50.7

Sources: Statisztikai Evkönyv 1977 (Statistical Yearbook 1977), Budapest, 1978. Statistical Pocket Book of Hungary 1978, Budapest, 1978.

In 1977, the Hungarian Central Geological Board undertook a long-term metals exploration program. Hungarian Aluminum Trust (HAT) initiated the opening of several new high-capacity bauxite mines, and Hungary's alumina-producing capacities will be extended substantially. Development of the No. II copper mine at Recsk continued in 1977. Uranium was continued to be mined in the Mecsek Mountains at 1,000 meters below the surface. As in all the previous years, uranium production and utilization was not reported. Production of medium-grade iron ore in 1977, mostly in Rudabánya, totaled 525,000 thousand tons; higher-grade ore was still imported from the U.S.S.R. Manganese (run-of-mine) ore

Digitized by Google

production totaled 160,000 tons and the reported production of manganese ore concentrate was 120,000 tons. Lead and zinc ore production increased slightly from that of 1976, with mine ore output reaching 151,000 tons and ore concentrate 8,220 tons.[12]

The 1977 plan envisaged a 3.2% increase in the volume of metallurgical production. Crude steel output was to increase to 3,750,000 tons and rolled steel production was to increase 5%. The actual amount of rolled steel increased 8% from 2,857 million tons in 1976 to 3,077 million tons in 1977. The 1977 plans were almost fulfilled for major metallurgical products. The following tabulation shows the planned and the actual production of some of the metal commodities during 1976-77, in thousand tons.

Commodity	1976	1977		Actual increase (percent)
	Actual	Planned	Actual	
Pig iron	2,221	2,300	2,286	2.9
Crude steel	3,652	3,750	3,723	1.9
Rolled steel	2,857	3,000	3,077	7.7
Hot-rolled steel pipe	184	185	186	1.1
Alumina	732	785	783	7.0
Aluminum ingot	70.5	71.5	71.3	1.1
Aluminum semifinished products	154	135.7	160	3.9

Source: Modification of data given in Kohászat (Metallurgy), Budapest. V. 3, No. 8, 1978, pp. 336-370.

Coal and lignite production in 1977 reached 25,454,000 tons, exceeding only slightly that of the previous year. However, a substantial growth in production is expected from the opening of new mines under the Eocene Program.

A noticeable rise in production of the nonmetallic minerals was achieved in 1977. This was mostly owing to the marked increase in the production of glass sand at the Fehérvárcsurgó plant and perlite at the Pálháza works.

Mining Investment and Exploration.—Hungary's mining investment and development objectives are not as much concerned with the opening of new mines as they are with the eventual processing and production of finished and semifinished products. This especially applies to the manufacture of materials from nonmetallic minerals, primarily dolomite, kaolin, industrial sands, siliceous earth, perlite, and bentonite. The Hungarian mineral industry concentrated on increasing investments in mining aimed at producing more solid fuels in 1977. Coal prospecting in new areas, for example, increased and a program for more efficient exploitation of known mines was initiated in order to raise their capacities through mechanization and improved management. It is estimated that 1,500 million tons of coal may be available as additional reserves, with further exploration needed for their location and extraction. To achieve this, more than 90 kilometers of exploratory drilling is envisaged during the current 5-year plan. Investments were also funneled into oil, gas, copper, and bauxite prospecting and production.

The investment trend of the Hungarian mineral industry since 1965 is shown in the following tabulation:

Industry	Percent			1977 at current prices	
	1966-70	1971-75	1977	Billion forints	Percent of 1976
Industry total	100.0	100.0	100.0	57.7	128.3
Of which:					
Mining	15.1	9.5	9.9	7.6	125.4
Metallurgy	11.1	7.8	7.1	5.3	142.9

Sources: Statisztikai Evkönyv 1977 (Statistical Yearbook 1977), Budapest, 1978. Statistical Pocket Book of Hungary 1978, Budapest, 1978.

Digitized by Google

In 1977, Hungary spent approximately Ft2 billion on geological exploration alone, with satisfactory results. This exploration program was directed at the discovery of new mineral deposits and the detailed exploration of the already known mineral deposits. Reserves of newly discovered minerals have grown faster than production. Seventy-three percent of the expenses were for exploration of new oil and gasfields, 24% for coal and bauxite, and 3% for precious metals and nonmetals. The immediate requirements for oil, gas, and bauxite spurred these large investments, while the moderate coal exploration expenditures were owing to the availability of known and relatively abundant reserves.

The Hungarian Aluminum Trust (HAT), especially the Bauxite Exploratory Enterprise, initiated in 1977 a program of improving the management of aluminum production and the exploration and delineation of new ore deposits. The latter, for example, drilled almost 10 kilometers of prospecting holes in 1977.

Development of the copper mine at Recsk proceeded in 1977 at an accelerated pace. The discovery of the porphyry ore at Recsk, and the fact that it occurs within the Drano Line, a major tectonic zone, has sparked a regional exploration and mineral search along this extensive fault structure.

Exploration for rare metals continued as planned. As part of this program, the 6th International Conference on Rare Metals was held in Budapest in 1977. Most of the rare metals exploration was conducted by the Mecsek Ore Mines, under the sponsorship of the International Atomic Energy Agency. Exploration for uranium steadily continued in 1977, under close supervision by the U.S.S.R. As before, all of the uranium ore was sent to the U.S.S.R. for processing.

The Hungarian Oil and Gas Trust (OKGT), which consists of some 27 enterprises, is responsible for exploration, production, processing, and marketing activities of petroleum and natural gas. As a result of its geological exploration, 60% of a planned 10-year program could be accomplished by the beginning of 1978. By the end of the current 5-year plan period, Ft40 billion may be invested by the Trust in order to accomplish the projected exploration and development program. For example, in addition to the 55 areas explored in 1976, exploration of 48 new oil and gas targets began to be explored in 1977 and final surveys were concluded on seven producing areas. The latter included Mihályi (gas), Pusztaapáti (oil), Harta (gas), Csanádapáca (oil and gas), Nagykörü (gas), northern Kiskunhalas (oil and gas), and Pátró (gas). A total of 370,000 meters was drilled for oil and gas in 1977, in comparison to 336,000 meters in 1976. Of these, 272 were of medium depth, 22 were shallow, and 76 were deep wells, 3 of which were classified as "very deep." The average depth of wells in 1977 was 2,199 meters versus 2,228 meters in 1976.

Table 1.—Hungary: Production of mineral commodities

(Metric tons unless otherwise specified)

Commodity[1]	1975	1976	1977[p]

Total	do	r70,563	r72,925	71,795

eEstimated. pPreliminary. rRevised.

[1]In addition to the commodities listed, diatomite, gypsum, and other crude construction materials such as common clay are produced, but available information is inadequate to make reliable estimates of output levels.

[2]Revised to zero.

[3]Ore contains 18% to 20% manganese.

[4]Excludes refinery fuel and losses.

[5]Figure derived from a reported total for light refinery products by subtracting motor gasoline and white spirit (each reported separately) from reported total.

TRADE

Hungary's national economy is strongly foreign trade oriented, with 45% of the national income realized through foreign trade transactions. Hungarian trade in 1977 with centrally planned economy countries accounted for 57% (53% with CMEA nations); Western-developed countries, 34%; and developing countries, 9%. In 1977, trade turnover (exports and imports) increased by 16% to Ft506 billion in current prices, with imports surpassing exports by 6%. Trade with centrally planned economy countries continued to grow (16%) in 1977, at 14% for imports and 19% for exports. Exports to market-economy countries increased 12% from that of 1976, while imports increased 19%. Hungary in 1977 had a total foreign trade deficit of Ft29 billion, most of it from the market-economy (dollar) countries. The anticipated signing in 1978 of a bilateral U.S.-Hungarian Trade Agreement, providing for Most Favored Nation (MFN) tariff status will open up new trade opportunities in manufactured goods with a Western country. Bilateral trade may increase significantly in 1978 as the effects of the trade agreement become apparent. In 1977, U.S.-Hungarian trade was close to $211 million. Hungary imported almost $155 million worth of U.S. goods and exported $56 million worth to the United States. Overall, however, the United States share in Hungarian foreign trade in 1977 was extremely small (2% of total imports and 1% of exports).

In 1977, exports of metallurgical products to centrally planned economy countries increased 10%. Exports of ferrous metallurgical products to the U.S.S.R. increased more than 15%. Steel slabs were imported and in exchange sheet products were exported (the Danube Iron Works more than doubled their sheet goods exports). Exports to other countries also increased by 11%. Total exports of ferrous products to market-economy countries decreased 1% in 1977. Overall exports of ferrous products, however, increased 16,000 tons or 2%, even though export of rolled steel decreased from 801,000 tons in 1976 to 784,000 tons in 1977. Exports of bar-section products increased from 480,000 to 520,000 tons or 8% in 1977, while exports of sheet products dropped from 280,000 tons in 1976 to 236,000 tons or 16%

Digitized by Google

in 1977. Exports of aluminum products in 1977 increased 35%, and exports of other nonferrous metal products increased 47%. Exports of aluminum products to the United States increased 29% in 1977.

The extent to which the 1977 price reductions affected the Hungarian ferrous metallurgical industry varied, but the metallurgical plants at Ózd (OKU) were the most severely hit. The price slump affected all their products, most of all the production of cable, since this product was in great demand worldwide. The 1977 profit of OKU decreased nearly 25% because of the unfavorable price situation. On the other hand, because of favorable market price situations, profits of the aluminum and other brands of nonferrous products developed as planned, with a favorable increase.

The U.S.S.R. is in first place in Hungarian foreign trade, with a 30% to 32% share. The largest export item to the U.S.S.R. is machinery and equipment, comprising approximately 35% of the total. Exports of rolling mill equipment were valued at Ft321 million in 1977 and metal working machinery at Ft659 million. The total value of Hungarian exports to the U.S.S.R was Ft3 billion.[13]

To meet Hungary's continuously rising demand for coal, petroleum, and natural gas, imports of the commodities were also increased during 1977. Rising prices for raw materials and fuels worldwide detrimentally affected the Hungarian economy in 1977 owing to the fact that 60% of all commodities have to be imported. Because of this, Hungary in 1977 initiated and imposed strict fuel consumption measures and regulations together with the reactivation of some mines and the introduction of improved management programs.

In addition to the import of large quantities of oil and gas from the U.S.S.R., various other raw materials are also imported such as the nonferrous metals, aluminum, rolled steel, and industrial timber. Import of mining machinery from the U.S.S.R. in 1977 amounted to Ft167 million. In 1978, Hungary plans to import 1 million tons of bituminous coal and coke from the U.S.S.R., most of its additional iron ore requirements, 6,500,000 tons of rolled steel, 15,000 tons of copper, 11,000 tons of lead, and many other nonferrous metals (including apatite concentrate and various finished fertilizers). As mentioned elsewhere, 4.4 billion kilowatthours of electrical energy is also to be imported from the U.S.S.R.[14]

Two-thirds of all Hungary's consumer goods are imported from the centrally planned economy countries from which Hungary plans to import 11% more goods in 1978 than in 1976. However, imports from the market-economy countries may increase by 7% to 8%. Imported goods make up more than 18% of all retail trade in Hungary.[15]

Table 2.—Hungary: Exports of mineral commodities[1]

(Metric tons unless otherwise specified)

Commodity	1975	1976	Principal destinations, 1976
METALS			
Aluminum:			
Bauxite[2]	602,635	633,108	Czechoslovakia 328,680; East Germany 190,023; Poland 110,070.

COMMODITY REVIEW

METALS

Aluminum.—Hungary in 1977 ranked 3rd in Europe and 7th in the world (3.6% of world output) in annual production of bauxite, 4th in Europe and 10th in the world (2.6%) in alumina, and 17th in Europe and 29th in the world (0.5%) in the production of aluminum. Hungary's bauxite reserves are a great national asset, despite the fact that the ore is only of medium grade, containing relatively high amounts of silica.

Production of bauxite in 1977 was almost 3 million tons, with little change from that of 1976. The production of alumina increased by 51,000 tons to 783,000 tons in 1977. Some analysts foresee an eventual production of 3.6 million tons per year of bauxite and 1 million tons per year of alumina, based on the present reserves. Hungary produced 71,335 tons of primary aluminum in 1977, compared with 70,499 tons in 1976. The major part of the 1977 bauxite production was processed to alumina, and 633,000 tons were exported. Hungarian aluminum smelters have an annual capacity of 70,000 tons, with no substantial changes foreseen in the immediate future. Since the 1962 long-term reciprocal agreement, shipments of alumina to the U.S.S.R. have grown steadily to a peak of 330,000 tons per year. After the alumina is smelted in the Volgograd Aluminum Works, the aluminum ingots (about 150,000 tons in 1977) are shipped back to Hungary as payment for its alumina. Because of high electrical power requirements (the electrolytic extraction of aluminum from alumina uses 15,000 to 16,000 kilowatt-hours of power per ton of

Digitized by Google

aluminum metal) Hungary does not intend to expand its domestic smelters in the near future, but instead will seek CMEA agreements under which alumina will be shipped to other countries and then aluminum returned to Hungary for further processing. Hungary's consumption of aluminum was 292,939 tons in 1977 compared with 285,418 tons in 1976. Hungary's per capita domestic aluminum consumption in 1977 was about 13 kilograms. This consumption is expected to reach 20 kilograms by 1980 and 30 kilograms by 1990.

The Hungarian aluminum industry employs more than 20,0000 people, most of them working for the Hungarian Aluminum Trust (HAT). In 1977, as in the previous several years, the emphasis was on increased bauxite output and improved methods of alumina production. Reportedly, in the future, the attention will focus on the production of aluminum semifinished products. This will include the expansion of the Székesfehérvár light metal works. The annual output of rolled stock is to be raised by 43,500 tons of pressed and 21,000 tons of drawn products. Nine investment projects are also underway, the most significant being the plan to increase the capacity of the Ajka alumina factory by 80,000 tons and the construction of a foundry with a 2,700-ton-per-year-capacity. Two other investment projects include the 5,000-ton aluminum foil plant at the Köbánya metal works and the development of aluminum sulfate production at Magyaróvár. Most of these projects will be financed through loans to the State Development Bank of Hungary, made by the CMEA Investment Bank of Moscow, in the amount of Ft1.9 billion.[16] In general, the overall output by primary smelters lags behind production of most of the major aluminum-producing countries. For example, it has been 25 years since the last smelter was built in Hungary. Technical development began in the mid-1960's and by 1975 rolling mill output had reached 136,000 tons per year. The last stage of this expansion will start in 1978, after which production is expected to increase to 120,000 tons per year of rolled products, 58,000 to 60,000 tons of extrusions, and some 65,000 to 70,000 tons of wire. By the mid-1980's, the country's semifabricating capacity is expected to total 240,000 to 250,000 tons and perhaps double between 1990 and 2000.

The goal of the Hungarian bauxite mining is to stabilize production at the level of 3 to 3.5 million tons per year for a considerable time. At the present rate of mining, the deposits already discovered may be sufficient for several decades. In order to insure this long-range supply, known mining deposits are being reexamined and new exploration surveys have been initiated so that new mines may be opened such as those planned at Nagyegyhaza, Fenyöfö, and Nyirád. Bauxite is found primarily in the Bakony-Vértes highlands and occurs in sedimentary rocks of marine origin. Deposits are located conveniently close to the coal reserves and to the Danube River, thus being near the energy resources necessary for its processing and the eventual transport of the ore. The most significant occurrences of bauxite are in Vértes (near Gánt) and the Bakony Mountains (near Iskaszenterdö, Halimba, Iharkút, and Nyirád). The bauxites here overlay the dolomites and are capped by Lower Eocene strata, which in some localities are also coal bearing.

Prior to 1945, most of Hungary's bauxite ore was strip mined, but now the better ore is extracted mostly from underground operations. Workable ore deposits suitable for Bayer processing occur at depths of 150 to 300 meters or even deeper and the ore is of medium grade, the Al_2O_3:SiO_2 ratio being 7 to 8. However, unless special precautions are taken, the mines may be flooded permanently, requiring the lowering of the water level below the working access at considerable expense. Because Hungarian bauxite ores are of medium grade and the cost of underground operations is more than for strip mining, there was no other practical alternative than to modify the conventional process. This was supposedly successfully accomplished and the present production costs are competitive on the world market. Furthermore, four of Hungary's deposits may be mined out by 1978 and three others by 1982 and 1985.[17]

Plans for 1978 include development of an open pit bauxite mine at Iharkút, in the Veszprém province of northwestern Hungary. The deposit will be mined by the Bakony Bauxite Mining Enterprise over the next 5 years. Two other development projects scheduled for 1978 are the opening of the Bitó-2 mine at Kincsesbánya and the Deáki mine at Nyirád, with projected annual output of 500,000 and 660,500 tons of bauxite, respectively. With Soviet help, construction of the coal-bauxite mine at

Digitized by Google

Nagyegyháza proceeded. Four exploratory shafts were sunk for the delineation of the potential 52-million-ton coal and 10-million-ton bauxite reserves. Mining of bauxite is to begin in 1981, and of coal in 1982, with the daily extraction of 2,000 tons and 6,000 tons, respectively.

In 1977, Hungary continued to help Yugoslavia in development of new bauxite mines and alumina production plants. This technical assistance program amounted to approximately $50 million since its inception in 1976. Hungary also receives special aluminum sheets from Czechoslovakia, the German Democratic Republic, and Austria in return for its semifabricated products exported to those countries. Negotiations were initiated in 1977 with Greece and the United States for various trade and cooperative agreements. The Aluterv Corp. of Hungary has been designing a 200,000-ton-capacity alumina plant to be built in Korba, India, and its eventual expansion. Hungarian enterprises were also supplying equipment and technicians for an alumina plant being built at Obrovac in Yugoslavia. At the request of the Leningrad Institute, the Aluterv Corp. designed another 600,000-ton-per-year-capacity plant to be built at Zvornik in Yugoslavia.

Exports of Hungarian aluminum to market-economy countries increased to $120 million in 1977, a 16% increase from that of the preceeding year. Total exports of ingots alone were 68,000 tons in 1977.[18] Most of the Hungarian aluminum is exported as semifinished and finished products, which in 1977 amounted to 30% to 35% of the total output. The major aluminum export items are motor castings, cables and conductors, window and door frames, kitchenware, liquid gas cylinders, collapsible tubes, and aerosol cans. Sales of bulk aluminum to Japan amounted to $1.5 million, compared with purchases of various goods from Japan on the order of $65 million. It is anticipated that 1978 export of combined goods to Japan will increase to 30%.

Copper.—Hungary's estimated 1977 mine output of contained copper was 1,010 tons, while 5,055 tons of copper concentrates were processed (a decrease of 26%). The declining trend of copper concentrate production has continued since 1975, when it was 7,018 tons. Hungary imported 50,000 tons of copper metal and products (up 18% from 1976) in 1977.[19]

Exploration for copper in 1977 continued in the Recsk area, Mátra Mountains, near the old Lahóca mine. According to some estimates, up to 2,500,000 tons of ore may be mined at 1.3% copper content; most of the ore grade, however, was averaging 0.4% to 0.7%. This expansion, including a concentrator and a smelter, may cost more than Ft20 billion. According to the present plans, the Recsk mine should be opened for operation in 1985 and full production is not expected to be attained until 1990. The project has been budgeted at Ft1.7 billion under the current 5-year (1976-80) plan, a record investment in Hungarian mining. Pyrite, lead, and zinc are also found at Recsk and are planned to be produced. Molybdenum content of the ore is about 60 parts per million, so that a 24% copper concentrate would contain 0.2% molybdenum which is recoverable. Rhenium also could be recovered from the Recsk concentrate, as a byproduct of the molybdenite concentrate.[20] Copper in the form of porphyritic chalcopyrite was found first at Recsk in 1967, which reportedly ranks among the top 20 deposits in the world. The top of the ore body is about 600 meters below surface. It is unique in that the central intrusive andesite ore body (chalcopyrite-copper-molybdenum porphyry) is zonally surrounded by an altered Triassic limestone (skarn) and mixed sulfide (Zn, Pb, Cu) ore mineralization. First drilling tests began in 1965, at a cost of several million forints. The Recsk mine is to be the deepest and the largest mine in Hungary. The old copper and gold mine at Lahóca is still in operation, but its output is decreasing rapidly, and most of its workers have been employed for years in the development of the new copper mine. Two vertical shafts, 8 meters in diameter each, have been sunk to a 1,200-meter depth. There will eventually be three levels at depths of 500, 700, and 900 meters (and perhaps even 1,200 meters) below datum. The work done has already involved the drilling of holes totaling more than 200 kilometers on a 250-meter grid. There are 135 holes with depths of 1,000 to 1,200 meters. Water is not a problem at Recsk, but high temperatures (to 51.5° C on the 900-meter level) may pose a problem, requiring intensive refrigeration and air conditioning. Most of the equipment suitable for mining under such conditions is not available in Hungary or in other CMEA

Digitized by Google

countries. At present, Finnish, British, and Soviet machinery is being used in the development of the mine. In addition to the mine, a mill, a smelter, and possibly a sulfuric acid plant are to be built on the Recsk site. The construction of a smelter is under serious consideration; the most troublesome issue in its development, however, is the environmental consideration. The smelter complex is to be located in a recreational area in a narrow valley about 1 kilometer from the mine, which many environmentalists consider is too small and shallow for efficient desulfurization. However, the advantage of a smelter, and also a concentrator, in the immediate area of the mine may overweigh the environmental restrictions.

Gallium.—Production of gallium in 1977 was estimated at 2.8 tons (about 10% of the world production), an increase of 0.8 ton (40%) more than that of 1976. The gallium section of the Ajka alumina and aluminum plant produced more than half of Hungarian gallium and enlargement of the section continued in 1977. In 1977, Hungary planned to export 500 kilograms of gallium from Ajka to the U.S.S.R. The gallium production section at the Almásfüzitö alumina plant, based on Soviet technology, was under construction in 1977 and completion was slated for 1979.[21]

Gold.—Gold is produced as a byproduct of nonferrous metal mining. The largest gold producer is the old Lahóca mine near Recsk, which is now almost depleted. However, the new copper mine under development at Recsk may become a new source of Hungarian gold.

The Hungarian State mint processes about 2 tons of gold annually for domestic consumption and 100 kilograms for export. According to Hungarian reports, the volume of gold offered increases 15% each year. In 1975, retail outlets sold 610,000 pieces (no other quantities are available) of jewelry and objects made of gold.[22]

Iron Ore.—In 1977, iron ore production was 524,832 tons, including 52,000 tons of oxidized and 473,000 tons of sideritic iron ore (with a metal content of 116,000 tons). This is a 13% decline from the 1976 production and a 18% decline from the 1975 output. Most of the higher grade ore (4.3 million tons) was imported in 1977 from the U.S.S.R. Iron ore in Hungary has been mined for years in Rudabánya, approximately 35 kilometers northwest of Miskolc, in the northeastern part of the country. The iron ore is of hydrothermal origin and is of the ferrogenous or sideritic and limonitic (oxidized) type.

Iron and Steel.—In 1977, Hungary produced 2.3 million tons of pig iron, 3.7 million tons of crude steel, and 3.1 million tons of rolled steel products. Consumption of steel was 2.9 million tons in 1977, a 0.6% increase over that of the previous year. Most of the steel went into construction and manufacture of machinery, followed by the transportation industry. The following tabulation shows the 1974-77 trends in Hungarian iron and steel production:

	1974	1975	1976	1977
Pig iron production:				
Thousand tons	2,301	2,219	2,221	2,286
Percent change from previous year	+6.9	-3.6	--	+2.9
Crude steel production:				
Thousand tons	3,468	3,673	3,652	3,723
Percent change from previous year	+4.2	+5.9	-0.6	+1.9
Share of oxygen enrichment steel (percent)	46.0	46.1	43.6	87.9
Share of steel continuously cast (percent)	12.1	21.1	27.9	28.3
Hot-rolled steel production:				
Thousand tons	2,392	2,675	2,857	3,077
Percent change from previous year	+4.8	+11.8	+6.8	+7.7
Share of flat-rolled products (percent)	38.3	39.3	38.2	43.5
Steel castings, thousand tons	NA	57	60	59
Steel forgings, thousand tons	NA	162	164	159

The ferrous metallurgical industry in 1977 had slightly overtaken its 1976 production in terms of tonnage. However, completion of many planned projects was delayed, mostly because the industry had undertaken more than it could handle. Wage increases in the metallurgical industry in 1977 averaged 7.5% to 9.0%. The iron and steel industry employed 79,100 people in 1977. The 1976-77 capital investment by various production sectors is shown in the following tabulation, in million forints:

Sector	1976	1977
Charge preparation	120	100
Pig iron production	150	130
Crude steel production	1,330	2,440
Steel rolling and finishing	375	420
Other installations	2,225	3,010
Total	4,200	6,100

Source: United Nations, Secretariat of the Economic Commission for Europe, Steel Committee, New York, WP. 1/R. 6/Add. 3, 1978, p. 8.

Of the total of 3,723,000 metric tons of raw steel in 1977, 3,307,000 tons were produced by the open-hearth process (89%) and 336,000 tons by the electric process. None of the steel in Hungary is produced by the Bessemer or the oxygen converter processes.

The country's three largest iron and steel enterprises, the Ózd Works, the Danube Iron Works (at Dunaújváros), and the Lenin Works (at Diósgyör) had a combined output of 3,723,000 tons of crude steel in 1977. These plants are undergoing modernization and when completed in 1981-82 their combined output will be increased by 1 million tons of steel annually. Since 1970, the annual growth rate of production has been only 3.8%. The expansion of open-hearth production with oxygen enrichment at the Ózd Works, which is to be completed in June of 1978, is to increase the works annual output from 1,100,000 to 1,400,000 tons. Most of the equipment for the oxygen plant, at a cost of Ft2.2 billion, has been imported from the German Democratic Republic and the smoke, gas, and dust separators have been supplied by the Federal Republic of Germany firm of Lurgi.

Plans for the installation of oxygen converters at the Lenin (Diósgyör) and Danube plants were made in 1976. Oxygen converter steel production is to be introduced to replace open-hearth production, and construction of the two units for this purpose is among the largest projects of the fifth 5-year plan. The unit at the Danube works will cost 9.4 billion forints and the unit at the Lenin works will cost 10 billion. The project will improve the quality of steel made at the Danube works, and it will increase the works' output by 64% from 1,100,000 to 1,800,000 tons. One of them will be completed in December 1981 and the other a year later. The designs and equipment will be supplied by the U.S.S.R. and the Federal Republic of Germany. An 80-ton-capacity oxygen converter with an annual capacity of 220,000 tons and an 80-ton electric furnace with a capacity of 200,000 tons per year are being built to replace the obsolete open-hearth furnaces at the Lenin works. A unit to produce high-quality steel is also to be installed. The equipment for the converter and for the steel shop are to be supplied by the Demag Company of the Federal Republic of Germany.

Construction of the two 130-ton Linz-Donawitz converters began in January 1977. The converters and the high-quality steel production unit (two 960-cubic-meter blast furnaces and one 1,700-cubic-meter furnace) are to be put into operation in October 1980; the electric furnace and a continuous casting unit is to begin operation in December 1982.[23]

The Csepel Metallurgical Works (CSW) produced over 3,000 tons more steel than planned in 1977 and its exports were 13% greater than in 1976. The enterprise's output value was reportedly Ft740 million more than in 1976. Csepel Iron and Steel Enterprise is also Hungary's largest producer of nonferrous metals, accounting for more than one-third of CSW's total production. The Csepel Nonferrous Plant intends to invest more than Ft2 billion during the current 5-year plan, so that its production will grow by 44% in 5 years.[24]

1977 was the first year of the 1976 Hungarian-Soviet metals agreement, pertaining to ferrous metal production during the 1976-80 period. Under this 5-year agreement, the U.S.S.R. will increase the yearly delivery of rolled steel to Hungary by approximately 600,000 to 650,000 tons and pig iron by 250,000 tons.[25]

Most of the raw materials processed by the Hungarian ferrous industry are imported. For example, some 4.3 million tons of iron ore and 1.2 million tons of coke are purchased annually from abroad, primarily from the U.S.S.R. Exports of rolled steel to

Digitized by Google

market-economy countries exceeded 1 million tons in 1977 while 544,000 tons of rolled goods were imported. Hungary imports 86% of its iron ore, 70% of its coke, and 82% of its alloying materials. Imports of crude steel in 1977 were six times that of the previous year (42,858,000 tons).

The following tabulation shows the 1976-77 import statistics for iron and ferrous metals, in tons:

	1976	1977
Iron ore	4,234,000	4,258,000
Pig iron	288,052	227,435
Ferroalloys	65,207	58,811
Crude steel	7,162	42,858

Besides the export of 1,128,581 tons of rolled steel in 1977, Hungary also exported other steel products, as shown in the following tabulation, in tons:

	1976	1977
Hot-rolled semifinished steel products	40,000	28,000
Steel sheets	355,000	343,000
Steel tubes	54,602	53,014

Under the 1976-80 plan, the annual production of steel is to total 4,300,000 to 4,500,000 tons and 3,100,000 to 3,300,000 tons of rolled products. In 1978, almost 2,500,000 tons of pig iron and more than 3,500,000 tons of steel are to be produced and about Ft7 billion is to be invested on the modernization of the ferrous industry. Emphasis in 1978 will be placed on completion of industrial projects that will boost exports and meet the diversified needs of the domestic market.

Lead and Zinc.—The production of lead-zinc ore was 150,877 tons in 1977, reflecting a 5% (7,200 tons) upward change from 1976, but still supplying only a fraction of the country's domestic requirements.[26]

Most of the ore was mined at the Gyöngyösoroszi mine, near Recsk, in the Mátra Mountains, in northern Hungary, from which concentrates were sent to Poland and Bulgaria for smelting. This mine produces about 150,000 tons of ore per year. The opening of another lead-zinc mine is planned as part of the Recsk copper mine development, with an annual capacity of 1 to 1.5 million tons of crude ore, thus insuring 75% of domestic needs by 1990. However, sufficient resources supposedly are not available to open such a mine before the second half of the 1980's. No significant change in lead-zinc production change is anticipated in 1978. The following tabulation summarizes the 1975-77 statistics for lead and zinc, in tons:

	1975	1976	1977
Lead-zinc ore	146,649	143,655	150,877
Lead concentrate	1,773	1,711	2,550
Lead, mine output, metal content	887	850	1,275
Zinc concentrate	4,319	4,324	5,670
Zinc, mine output, metal content	2,160	2,162	2,835

Manganese.—Hungary produced 160,637 tons of manganese ore in 1977, of which 125,260 tons was oxide ore and 35,367 tons was carbonate. In the former case, there was a production increase of 10,000 tons, while in the latter there was a decrease of 16,000 tons compared with that of 1976. Part of the concentrated manganese ore was exported to the Federal Republic of Germany, Yugoslavia, and Poland.

In 1977, manganese ore continued to be mined at Úrkut, in the Transdanubia region. Hungary's estimated reserves of mostly carbonated manganese ore is 80 to 100 million tons. In the past 10 years, production has decreased to about 50% because domestic output of ferromanganese has virtually ended for environmental protection reasons. The incentive of an increase in the world market prices for manganese and especially ferromanganese in the past 2 or 3 years, however, has stimulated the investment potential by this industry. Thus, a new 35,000-ton-capacity plant is to be constructed in the future at a cost of Ft3 billion.

The following tabulation summarizes the 1975-77 statistics for manganese, in tons:

	1975	1976	1977
Oxide ore	127,660	114,450	125,260
Carbonate ore	54,705	50,624	35,367
Total	182,365	165,074	160,637
Manganese concentrate	131,000	125,000	120,000

Silver.—Silver is produced as a byproduct of nonferrous metal mining. The output of silver has been increasing slightly but steadily since 1974. The copper mine presently under development at Recsek may become a new source of Hungarian silver.

Titanium.—Hungary still does not have any titanium mines, even though there are

Digitized by Google

a number of prospective ore deposits. The most significant is the wehrlite stock of Szarvaskö in the Matray/Tokaj Mountains of magmatic and partly hydrothermal origin.[27]

NONMETALS

The production of nonmetallic minerals increased in 1977, including such commodities as cement, bentonite, perlite, and glass and foundry sand. Hungary satisfies its domestic demand for most raw nonmetallic minerals and even exports some of them. More efficient domestic production of such minerals as dolomite, kaolin, and bentonite is also being planned. Most of this investment is to be in the improvement of processing technology and product diversification, which have not kept pace with the changing consumer demands.

Cement.—Hungary produced 4.6 million tons of cement in 1977, 7.5% higher than the 1976 production. During the year, cement was not readily available and there was a decline in prices, caused by fluctuating seasonal demand, storage problems, and low productivity.[28] Another cause of the cement shortage was inadequate transportation. For example, the Hejöcsaba cement plant was built at the edge of Miskolc partly because of the already existing rail system. About Ft100 million were spent on developing the freight yard. In 1977, the amount of stored cement at the Hejöcsaba plant began to grow, and by mid-summer, the Hungarian State Railroad (MAV) was unable to furnish the required daily 500 to 600 freight cars for the transport of 5,000 to 6,500 tons of cement. Instead, the plant informed its customers to pick up the cement themselves. Some 400 to 500 trucks per day came from Bácska, Szablocs, and Alföld, lining up at the plant gate the night before for loading the next morning. Because the plant begins full operation in 1978, this situation may be expected to worsen.[29] Partly because of this, several new cement plants were commissioned in 1977, and production and delivery schedules were tightened. Total consumption in 1977 was 5,111,000 tons, with per capita consumption being 482 kilograms. Hungary plans to produce 6 million tons of cement annually in 1980 and is expected to increase this to around 7 million tons annually by 1985. Imports and exports continued to increase in 1977 but at a lower rate than in the 1975-76 period, especially in the export sector. This stabilization in the export volumes is owing to the continued implementation of the 1976 foreign trade policy. In 1977, imports from the U.S.S.R., Romania, and the German Democratic Republic stood at 792,000,000 metric tons (up 4.5%) and total exports at 265,000 tons (up 18% from 1976 and up 71% from 1975).[30]

A new dry-process plant, designed to make Hungary self-sufficient in cement, was being built at Bélapátfalva in northern Hungary in 1977. It will be the fourth new dry-process plant built since 1960. The plant will cost some $220 million and is to produce 1.2 million tons of cement in 1978. Its two preheater kilns measure 5 by 75 meters and most of the plant's equipment came from the U.S.S.R. In 1977, trials began at a new prefabricated concrete plant at Bábolna, which will have an annual output of 3 million tons and will cost Ft165 million to build.[31]

Most of the newer cement plants in Hungary are located in the immediate area of ample limestone deposits (estimated reserves are sufficient for 40 to 70 years), and most of the fuels to fire the kilns come from the U.S.S.R. All cement plants in Hungary, except for the small experimental unit at Selyp, also produce lime as part of their operations.

In 1964, the Hungarian cement industry was reorganized and the 10 or so independent enterprises were merged into 1 central organization, Cement and Lime Works at Vac (Cement és Mészmüvek), under direct supervision of the Ministry of Construction. The following tabulation lists, and describes briefly, operational Hungarian cement plants:

Plant location	Annual capacity	Cost of construction[1]	Remarks
Bélapátfalva, 125 kilometers northeast of Budapest, near Miskolc	1.2 million tons	US$220 million Ft9 million.	To begin operating in 1978. Has two 5- by 75-meter preheaters. New dry process, oil and gas fuel.
Beremend, 45 kilometers south of Pecs	1.1 million tons	US$85 million Ft2.5 billion.	Began operating in 1972. Has two 4.4- by 65-meter kilns. Produces portland and blended (fly ash) cement. New dry process, oil fuel.

See footnotes at end of table.

Plant location	Annual capacity	Cost of construction[1]	Remarks
Hejöcsaba, 150 kilometers northeast of Budapest, near Miskolc	1.3 million tons	US$230 million Ft5 to 6 billion.	Began operating in 1975, replacing an old wet-process facility. Has two 4.6- by 60-meter Polysius kilns with Dopol suspension preheaters and planetary coolers. New dry process, natural gas fuel.
Lábatlan, 20 kilometers north of Tatabánya	500,000 tons	--	Began operating in 1952. A 5-kiln (rotary) old wet-process plant. May be eventually converted to the new dry process or to output of high-sulfate resistant portland cement. Uses coal fuel.
Selyp, 50 kilometers north of Budapest	60,000 tons	--	Built in 1967. Small experimental cement plant for special products. One old kiln. Uses coal fuel.
Tatabánya, 80 kilometers west of Budapest	500,000 tons	US$10 million. Renovated in 1959.	May close by 1990 owing to age and lack of local limestone supplies. Old wet-process rotary 5-kiln plant. Produces portland and blended (fly ash) cement. Uses gas and coal fuel.
Vác, 50 kilometers north of Budapest	1.2 million tons	US$40 million	Construction started in 1960, began operating in 1963, full capacity reached in 1965. Has three 4- by 60-meter Lepol kilns and one 4- by 60-meter Polysius-Dopol kiln. Produces portland and blended (blast furnace slag) cement. New dry process, oil fuel.

[1]U.S. dollars and Hungarian forints (Ft) have not been converted owing to the wide variation in official exchange rates and because the quoted figures have been compiled from various sources.

Under Hungary's sixth 5-year plan (1981-85), Hungary may install a fifth new dry-process plant in northern Transdanubia, where at present large limestone deposits are being studied. This expansion is designed to achieve the previously planned cement self-sufficiency goal of 6 million tons annually by 1980.[32]

Environmental protection now plays a decisive and central role in the Hungarian cement industry. All cement plants constructed in the fourth 5-year plan period have been fitted with modern dust-collector and dust-binding installations. Dust remains a prime concern both inside and outside cement plant operations. At the new and largest Hejöcsaba plant, for example, 13% of total investment was reportedly spent on the reduction of dust pollution.

Clays.—*Bentonite.*—Production of crude bentonite in Hungary was 80,003 tons in 1977, from which 51,636 tons of marketable product was produced. A wide range of bentonite clays are produced in Hungary for use as a foundry binder. With the exception of the natural, ground, calcium montmorillonite, all grades are produced by the sodium exchange technique and grinding. Two grades of soda-activated bentonite (good yield and low-water loss) are produced for use as well oil-drilling muds.

More than three-fourths of the bentonite is mined from an open pit at Hercegköves and from a smaller open pit in the Rátka Újhegy area, Zemplén Mountains of northeastern Hungary. All of the new bentonite is processed at Mád, together with the kaolin. New deposits found at Ond and Istenmezeje are still being examined for their eventual extraction.

Kaolin.—Production of kaolin declined in 1977 to 71,455 tons, 6,000 tons of which was processed. Almost all of the kaolin mines in Hungary are located on the southern and southeastern flanks of the Zemplén Mountains and kaolin is sometimes mined and processed at the same localities and plants as the bentonite. Most of the larger mines are open pit but the Szegilony and Füzérradvány mines are underground. The mined kaolin is processed locally at the Mád, Bodrogszegi, Szegi, and Erdöbénye plants. There are sufficient reserves of clays in Hungary to last for the next 20 to 25 years.

Diatomite.—A new plant producing calcined diatomaceous earth was under construction in 1977 in Erdóbénye. It is designed for producing plant insecticides for agri-

Digitized by Google

cultural use. Its production will result in considerable import savings. Most of Hungary's diatomite consists of the *Navicula* and *Melo sira* species of diatom, and the manufactured products are suitable for a wide range of applications.[33]

Fertilizer Materials.—In 1977 Hungary produced 679,000 tons of nitrogenous and phosphatic fertilizer materials, in terms of nutrient content. The production of nitrogenous fertilizer continued to rise, while phosphatic fertilizer output continued to decline. The total production of bulk fertilizer in 1977, including anhydrous ammonia, was 4,265,000 tons. The 1977 economic plan envisaged the production of 1.7 million tons of fertilizers in nutrient content, as contrasted to the 1.6 million tons of actual production.[34]

Hungary depends on imports for all of its potassic, most of its phosphatic, and some of its nitrogenous fertilizers. Some 55% of Hungary's requirement for fertilizer is now produced domestically, while 30% is imported from the centrally planned economy countries, 15% from the U.S.S.R., and some from Algeria; the potassic fertilizer comes from the German Democratic Republic and the U.S.S.R. Hungary exports large quantities of fertilizer mostly to the Federal Republic of Germany and Yugoslavia. The following tabulation shows 1975-77 import statistics and trends for phosphate rock and apatite concentrate in thousand tons:

	1975	1976	1977
Morocco	32,118	33,858	86,437
Algeria	52,545	71,841	109,854
Jordan	--	--	3,613
U.S.S.R. and Vietnam	617,702	398,146	446,512
Total	702,365	503,845	646,416

Source: Modification of data in British Sulfur Corporation Ltd., London, Report, 1977.

Pét Nitrogen Works, located in Pétfürdö near Varpalota southwest of Budapest, is the largest chemical fertilizer plant in Hungary. The plant was put into full operation in late 1977 and was expected to produce at least 600,000 tons of compound (NPK) fertilizers (containing nitrogen, phosphorus, potassium), 200,000 tons of urea (carbamide), 240,000 tons of calcium ammonium nitrate, and 220,000 tons of nitrogen.[35]

The other Hungarian fertilizer plants are the Borsod and Tisza chemical complexes, both located near Miskolc, northeast of Budapest. The Tisza chemical complex reported a production of 500,000 tons of ammonium nitrate in 1977, more than double that its first year of operation in 1964.[36] The Borsod chemical complex was nearing the completion of a large-scale reconstruction in 1977, which will enable the Kazincbarcika complex to produce 1,000 tons more ammonia and 2,800 tons more nitrogen fertilizer annually. It was reported, however, that construction of the Borsod chemical complex's No. 4 nitrogen plant was postponed for 1 year.[37]

In the 1985-90 period, Hungarian fertilizer consumption is expected to double, making it highly possible that imports will continue. According to the forecasts of various Hungarian institutions, the demand for fertilizers in terms of nutrient content should be 1.2 million tons by 1980, at 290 to 300 kilograms per hectare. This is expected to grow to 2.5 million tons by 1985 and 3 million tons by 1990. Hungarians expect that eventually the phosphate content of fertilizers will decline and that foliar fertilization and systematic micronutrient additions will become the general practice. The following tabulation shows the planned production of various fertilizers after 1980, in thousand tons of nutrient content:

	N	P_2O_5	K_2O	Total	Percent
Ammonium nitrate (34% N)	200	--	--	200	15.4
Calcium ammonium nitrate (25% N)	210	--	--	210	16.2
Urea (46% N)	170	--	--	170	13.1
Ammonium sulfate (20.5% N)	10	--	--	10	.8
Superphosphate (18% P_2O_5)	--	200	--	200	15.4
NPK 16-16-16	80	80	80	240	18.4
NPK 10-30-20	25	75	50	150	11.5
NPK 11-22-15	27.5	55	37.5	120	9.2
Total	722.5	410	167.5	1,300	100.0

Reportedly, a group of French companies has been awarded a contract by Hungary's Chemokomplex, valued at $5 million, to build a phosphoric acid plant and a 30,000-ton-per-year sodium tripolyphosphate plant at Szolnok, scheduled for completion in 1979. Elemental phosphorus will be supplied to the plant by the U.S.S.R. from Kara-tau.[38]

Perlite.—The production of perlite in 1977 increased to 103,270 tons or 270,000 cubic meters, mostly from the Pálháza works in the Zemplén Mountains. Reportedly, perlite reserves at Pálháza are sufficient to supply the building industry with basic insulating materials and cement admixtures until the end of this century. Hungary ranks fifth or sixth in the world in perlite production, making it a leading producer of this commodity. In 1977, 75% of perlite produced was exported to Austria and the German Democratic Republic. Because of the demand for perlite in the building industry and because Hungary is favored with plentiful reserves, perlite may in the near future be playing a more significant role in Hungary's overall economy. In addition to Pálháza, several mines are located at Teikibánya and Sátoraljaújhely, with processing plants at Belegrádpuszta, Zalaegerszeg, and Hegyalja regions. Mining at Pálháza began in 1954 as an open pit operation, as are most of perlite mines. The ore is blasted in shallow benches and then transported in trucks to crushing and sizing plants.

Sand and Gravel.—Production of glass and molding sand increased in 1977 by 30% and 7%, respectively, mostly owing to the expansion of the Fehérvárcsurgó plant. Production of building sand and gravel, on the other hand, decreased by 50% and 34%, respectively. A 50% production expansion of glass sand is planned for the current 5-year plan. In 1977, work continued at Pécsvárad on the plant processing sand with a high feldspar content designed for use by the ceramic industry.

MINERAL FUELS

The overwhelming majority of Hungary's energy is imported from the CMEA countries, primarily from the U.S.S.R. Additionally, lesser amounts are also imported from market economy countries. In 1977, coal accounted for 37% and oil and natural gas for 61% of all energy sources. Other energy sources, such as hydropower and fuelwood made up the remaining 2%.

Domestic production accounts for 60% of Hungary's energy sources and imports for 40%, primarily from the U.S.S.R. Coal mining output was 25.5 million tons, of which 8 million tons of lignite came from opencast mines, and 17 million tons of bituminous and brown coal came from underground mines. Oil refineries processed 72 million barrels of oil, the bulk of which was imported from the U.S.S.R., and 17 million barrels was produced domestically; 253,464 million cubic feet of natural gas was produced and an additional 42 billion cubic feet of gas was imported.

The total energy balance for 1976 and 1977 is shown in table 4.

Table 4.—Hungary: Primary energy balance for 1976 and 1977

(Million tons of standard coal equivalent[1])

Year	Total primary energy	Coal (lignite, anthracite, bituminous), coke, and briquets	Crude oil and petroleum products	Natural and associated gas	Fuelwood	Hydroelectric and other power
1976:						
Production	r26.5	r14.8	r3.2	r8.1	0.4	--
Imports	r18.1	r1.7	r14.3	r1.6	--	r.5
Exports	r.7	r--	r.6	r.1	--	--
Apparent consumption	r43.9	r16.5	r16.9	r9.6	.4	r.5
1977:p						
Production	27.3	14.9	3.2	8.8	.4	--
Imports	18.9	1.9	14.8	1.6	--	.6
Exports	.6	--	.5	.1	--	--
Apparent consumption	45.6	16.8	17.5	10.3	.4	.6

pPreliminary. rRevised.

[1]1 ton standard coal equivalent (SCE)=7,000,000 kilocalories. Conversion factors used are as follows: Hard coal, 1.0; lignite and brown coal, 0.5; recovered slurries, 0.515; briquets and household coke, 0.67; coke, 0.9; crude oil, 1.47; refinery products, 1.53; natural gas, 1.33 (per thousand cubic meters); manufactured gas, 0.6; and hydroelectric power, 0.125 (per thousand kilowatt-hours).

Digitized by Google

Energy consumption in 1977 was 4% more than that of 1976 and a similar increase is expected in 1978. Consumption statistics for the major energy sources are given in the following tabulation:

	1960	1970	1975	1976	1977
Coal ---------- million tons	28.1	29.6	26.6	27.3	27.4
Petroleum ---------- thousand tons	2,608	6,038	9,657	9,929	10,057
Natural gas ---------- million cubic meters	--	3,667	5,919	7,230	7,780

Sources: Statisztikai Evkönyv 1977 (Statistical Yearbook 1977), Budapest, 1978. Statistical Pocket Book of Hungary 1978, Budapest, 1978.

During the fifth 5-year plan period, Hungary intends to put 40% of its total investments into the energy sector. Furthermore, the Ministry of Heavy Industry, called for large-scale economy measures in power consumption by both the public and the industry. In the 1980's, the amount of liquid hydrocarbons consumed by the power stations is to be reduced and replaced by the greater use of coal and nuclear power. According to the Ministry, coal production in 1978 is expected to be approximately 25.4 million tons, petroleum production is expected to surpass 2.1 million tons, and natural gas production is expected to surpass 7 billion cubic meters.[39]

Hungary imports nearly 83,000 megawatt-hours of electric energy from Bulgaria, Romania, Czechoslovakia, Poland, and the German Democratic Republic, through the CMEA electrical energy system. In addition, almost 20% of the energy is acquired directly from the U.S.S.R. In 1977, work was nearing completion on a 750-kilovolt electric transmission line which will operate between Vinnyica and Albertirsa. Also nearing completion was the Orenburg ("Szövetség") natural gas pipeline (a CMEA project) and the Adriatic petroleum pipeline (a Yugoslavia-Czechoslovakia-Hungary project). The first 440-megawatt stage of the 1,760-megawatt nuclear power station at Paks, now under construction, is to go into operation by December 1980, and other plants are being planned.[40] Except for one 860-megawatt oil-fueled plant already under construction, it appears that no further power stations are to be built which depend either on hydrocarbon fuels or on imported coal.[41] The long-range outlook for the Hungarian economy is that its energy needs will double in one or two decades and that the entire proven fuel reserve is not even sufficient for the country's needs till the end of the century. Thus, the development of energy from new sources and with new methods is seriously considered by Hungary. One new source under consideration is geothermal energy. Nearly one-half (40,800 square kilometers) of Hungary's territory is suitable for the economic production of geothermal energy. The production is especially possible from the Upper Pannonian formations. Hot springs exist in more than two-thirds of the country, with water temperatures at 40°, 70°, and even 90° C.[42] Presently, Hungary has 500 operating geothermal wells and another 19,500 are possible. If the geothermal energy development program is implemented by 1985, it is expected to save Hungary 536,000 tons of oil.[43]

Coal.—In 1977, the production of all types of coal and lignite reached almost 25.5 million tons, exceeding that of 1976 only by 0.78%. A higher coal production was emphasized in 1977 owing to shortages and increasing fuel costs.

Hungarian coal and lignite reserves are estimated at 2.5 billion tons. Lignite west of the Danube can be strip mined and is older and of better quality than that east of it which occurs in Lower Tertiary Paleocene deposits. Two-thirds of Hungarian lignite is mined from this basin. The other one-third is made up of lignite and bituminous deposits from the Bakony region north of the Dunántúl highlands and from the southern foothills of Mátra and Bükk, northeast of Budapest.

Geological surveys and exploration programs for coal in 1977 were expedited in order to discover new deposits and to update the estimates of the known reserves. According to a geological survey, a good quality minable lignite deposit of 130 million tons was found at Mány, near Tatabánya. Tatabánya is the largest coal mining town in Hungary, having 73,000 inhabitants. To date, the Tatabánya coal basin has produc-

Digitized by Google

ed 160 million tons from 1 strip mine and 9 underground mines, worked by 13,000 miners. Annual production is about 2.5 million tons, but reserves are decreasing and mining is being shifted to the newly discovered Csordakút-Négyegyháza-Mány basin in Transdanubia. A 6-million-ton annual production is forecast from that field, which is part of the Eocene Program. Two other new lignite mines, with a total annual capacity of 8 million tons, were being developed in the Transdanubian region in 1977.

The shortage of railroad freight cars and coal storage space continued, causing a loss of more than 100,000 tons in deliveries in 1977. Three mines have also been closed in Borsod County. The county produced almost 5.3 million tons of coal in 1977 (200,000 tons more than planned) and projects production of 5,130,000 tons for 1978. Ultimately, the production of Hungarian coal is expected to increase to 30 million tons per year by 1980, a considerable increase from 24.9 million tons per year in 1975 when production was the lowest. In the long run, the production is envisaged to reach the 40-million-ton-per-year mark, even though 1978 production is expected to be only 26 million tons.

From the maximum coal production of 31.5 million tons in 1964-65, the demand for coal has dropped in subsequent years owing to the switch to the use of hydrocarbon energy. In the last few years, however, the demand for coal was on the upswing again and in order to prepare for this rejuvenated coal consumption, the Eocene Program has been initiated. Under this program, openings of new mines are planned which will boost the coal production in the next decade. This program will develop the brown coal deposits of Eocene and Miocene age in the Tatabánya area, the Pannonian (Pliocene) lignite deposits in the Mátra Mountains and the foreland of the Bükk Mountains, and the Liassic (Jurassic) coking coal in the Mecsek Mountains. Of these deposits, one-third is to be extracted by underground mining and two-thirds by open pit excavation. This program, for example, will replace the depleted coal reserves at Komárom Corontz and coal mining in the Tatabánya-Oroszlány-Dorog region will be renewed. Mines at Márkus-Hegy, Nagyegyháza, Mány and Lencse-Hegy II, and mines at Balinka and Dudar are expected to produce 9 million tons of coal per year (half of the production from the underground mines). Most of this lignite will be supplied to the thermal powerplants, such as the one at Bicske. The long-range prospects of the Eocene Program is to open new mines that will supply Hungary with coal and lignite for the next 100 years.[44]

The Eocene Program is Hungary's most ambitious and grandiose multimineral exploration and development program. In order to achieve raw mineral self-sufficiency, a broad cooperative thrust is being applied to mine more than one mineral from the same mine, such as coal and bauxite, for example. Besides these "two-product" mines, the development objectives also include the simultaneous construction of cement and alumina plants and electric powerplants near the new mines. Such multi-industry cooperation is expected to contribute to the country's domestic raw materials and energy independence. As a direct result of this program, the industrial growth of Komárom County, the geographical focal point of this development, has grown considerably. The first comprehensive study was completed in March 1970, which examined the feasibility of simultaneous mining of coal and bauxite occurring in the same stratigraphical section. One such area is the Csordakút-Nagyegyháza-Mány coal basin. Coal of Eocene age (hence, the Eocene Program) occurs here close to the surface and is separated from the Jurassic bauxite below by dolomite beds.[45] Thus, it is not the discovery of new deposits that may be so significant in the Eocene Program, as the cooperative mining and construction ventures.

Natural Gas.—In 1977, Hungary produced 253.5 billion cubic feet of natural gas and imported 42.7 billion cubic feet. Most of the gas (59%) was produced from the Szeged area in southeastern Hungary, in the immediate vicinity of the highest oil-producing Algyö field. Fields in the Szeged-Algyö region hold almost 50% of all the oil and more than 60% of gas reserves. In addition, small fields of natural gas, mostly associated with oil, exist all over Hungary. Some of the fields are in the northwest, essentially the continuation of the Vienna oil and gas basin; other gasfields are found even in the immediate vicinity of the capital and in the Tisza-Vasvár area in the northeast. On the basis of known reserves and present levels of consumption, oil and gas will be available for the next 20 years. In the long run, production of 2 million tons per year of oil

Digitized by Google

is foreseen.

Capital investment in the Hungarian gas industry for the 1976-80 period has been at a level of Ft20 billion. In addition to its domestic production, the Fraternity pipeline, opened in 1975, continues to steadily channel over 35.3 billion cubic feet of natural gas annually from the U.S.S.R. An additional 7.1 billion cubic feet is also received from Romania and large amounts will be delivered in 1978-79 through the Orenburg line from the U.S.S.R. Under that project, which is being completed with the participation of several CMEA countries, Hungary is to obtain more than 134 billion cubic feet of gas annually from the U.S.S.R. as compensation for its investment and work on the project.

In order to avert a gas shortage, an underground storage was completed at Pusztaederics in 1977. At the Ebes field, in the northern Great Plain, a natural gas processing plant was installed. Reportedly, the second natural gas processing unit of the Szeged Petroleum and Natural Gas Industrial Establishment processed 2.4 million cubic feet of propane-butane in 1977, compared with 1.7 million cubic feet in 1976. The plant invested Ft515 million into its natural gas processing unit No. II. Investment into the carbon dioxide enhanced recovery installations in the Lóvaszi field amounted to Ft123 million. The cost of three DHR-160 drilling rigs by the Lowlands Exploration and Development Establishment was Ft123 million. Only two small gasfields were developed in 1977, and their output was only slightly more than 35 million cubic feet.[46]

Petroleum.—In 1977, Hungary produced 2.2 million tons of oil. For domestic requirements, an additional 8.5 million tons were imported, primarily from the U.S.S.R. (7.7 million tons). The 2-million-ton-per-year production level was first reached in Hungary in 1975 and has since been increasing steadily. The four operating Hungarian oil refineries produced a total of 10 million tons of products in 1977, compared with 9.8 million tons in 1976.

Most of Hungarian oil reserves used to be concentrated in the southwestern part of the country, in the petroliferous region of Zala (Dunántúl), but these are now almost depleted. Presently, Nezötur, southeast of Budapest, and the Szeged-Algyö area in the south, are the main oil basins in the Great Alföld. Of the 2.2 million tons of oil produced in 1977, 48% came from the Algyö field. Production declined from the Transdanubia fields and from some of the smaller fields in the Great Hungarian Plain. This decline, however, was compensated by the increased production from the Szeged-Móraváros and Ferencszállás fields. Production losses in 1977 were cut by the introduction of new recovery techniques. The new method of oil displacement by carbon dioxide, for example, was in the advanced stage of development. This method was tested in the Szeged-Algyö fields in 1977 and almost 200 wells are to use this method by the end of 1978.

Production by refineries in 1977 remained almost at last year's level, with gasoline at 17 million barrels, residual fuel oil at 23 million barrels, and distillate fuel oil at 26 million barrels. Hungary relies heavily on the U.S.S.R. for crude oil supplies. Under a joint agreement, more than 40 million tons of crude oil are to be delivered by the U.S.S.R. to Hungary in 1976-80, with an additional 6 million tons of various crude oil products.

The throughput of operating crude oil pipeline systems (Friendship I, Friendship II, and Algyö-Százhalombatta) was increased in 1977 to 95% of their designed capacity. In addition, the Adriatic pipeline was in the final stages of completion and will contribute significantly to the oil transport in the future. The pipeline is being constructed in order to obtain additional supplies of petroleum from the Middle East and North Africa. Czechoslovakia and Yugoslavia are in partnership with Hungary in this joint venture. The pipeline's projected annual capacity is 34 million tons, with Hungary and Czechoslovakia receiving 5 million tons each, and the remaining 24 million tons going to Yugoslavia.

In 1977, one of the most significant projects was the commissioning of the Eastern Product Pipeline. This line is intended to transport the refined products imported from the U.S.S.R. to Hungary. Another important project (Ft112 million) was the construction of a gasoline processing unit at the Komárom Petroleum Refining Co., designed to produce high-octane gasoline. The company also commissioned the construction of three gas-oil storage tanks, at 20,000 cubic meters capacity each. At Tisza Petroleum Refining Co., four fuel oil tanks, at 30,000 cubic meters each, were also commissioned in 1977.

Domestic marketing of refined products

Digitized by Google

in Hungary is directed by the Mineral Oil Marketing Co. (AFOR). The oil and gas exports are carried out by several foreign trade companies, the Mineralimpex and Chemokomplex being the foremost.[47]

Uranium.—The search for radioactive minerals in Hungary began some 30 years ago in the Valence Mountains in the western part of the country. Subsequently, the areas of search have spread to Koszeg Mountains and to Pécs in the Mecsek area, under close Soviet supervision and support. In the Mecsek Mountains, ore is extracted from a depth of approximately 1,100 meters, concentrated in several sandstone horizons of Permian age. The Mecsek uranium mine is the second deepest mine in Hungary (the deepest, more than 1,200 meters, is the Recsk copper mine). The uranium mine, "Petöfi No.4/11th Congress Seam," located near Petoc in the Mecsek Mountains, was opened in 1971 after the closure of mine No. 1 by the Mecsek Ore Mining Enterprise due to depleted ore deposits. Mine No. 1 was the first mine where uranium was mined in Hungary in the early 1950's. The No. 4 mine is more than 1,000 meters deep and the miners work in temperatures of 42° C. More than 90% of the uranium is exported to the U.S.S.R. In order to increase production, development of the No. 5 uranium mine started in 1977.

The Mineral Industry of Iceland

By Joseph B. Huvos[1]

In 1977, Iceland, with no significant minerals but with abundant hydroelectric and geothermal energy, had a slightly improved economy, but inflation was at 31% and unemployment was maintained artificially at 0.5%.

The gross national product (GNP) was about $1.3 billion.[2 3] Two important events in Iceland's mineral industry during the year were the commissioning of a major hydroelectric project and continued construction of a State-controlled ferroalloy plant.

PRODUCTION AND TRADE

There was an increase in production of primary aluminum, Iceland's most valuable mineral product during the year. Production of mineral commodities is shown in table 1.

There was no significant change in Iceland's foreign trade pattern in 1977. Mineral commodity exports remained mainly aluminum and small amounts of scrap, cement, and diatomite. Principal mineral imports remained petroleum products, alumina, cryolite, and salt.

No mineral commodities were exported to the United States in 1976, and the major items of the small mineral imports from the United States were petroleum products and some steel semimanufactures and metals. Iceland's mineral commodity trade in 1975 and 1976 is shown in table 2, and trade with the United States in 1976 is shown in table 3.

Table 1.—Iceland: Production of mineral commodities

Commodity and unit of measure	1975	1976	1977[p]
Aluminum metal, primary ---- metric tons	61,800	65,300	72,800
Cement, hydraulic ---- thousand metric tons	159	145	139
Diatomite[1] ---- metric tons	20,264	22,699	20,985
Fertilizer materials, manufactured, gross weight:			
Nitrogenous ---- do	9,680	12,892	8,897
Other ---- do	[r]25,284	29,866	36,088

COMMODITY REVIEW

METALS

Aluminum.—During 1977, Norsk Hydro AS and the Icelandic Government discussed the possibility of building a 100,000-ton-per-year aluminum smelter at an unspecified location.

Work was underway to install a $36 million gas emission purification system at Alusuisse's Straumsvik plant, scheduled for completion in 1980. Alusuisse continued to operate the only aluminum reduction plant in Iceland, the 76,000-ton-per-year facility at Straumsvik, south of Reykjavik.

Ferroalloys.—Construction continued at Icelandic Alloy's Hvalfjördur ferroalloy plant north of Reykjavik, with production scheduled to start in 1979 at the rate of 25,000 tons per year and expected to increase to 50,000 tons later. The Icelandic State holds a majority interest in the company, with Elkem-Spigerverket A/S of Norway as the minority partner. National Power Co. held jointly by the State and the city of Reykjavik, is to supply the 68 megawatts of electric power needed to operate the plant.

NONMETALS

Cement.—Sementverksmidja Rikisins (Iceland State Cement Works) operated the country's only cement plant, located at Akranes near Reykjavik. The plant operated virtually at full capacity during the year.

Diatomite.—In 1977, repeated earthquakes damaged the Lake Myvatn diatomite plant, but production was not drastically interrupted. Controlling interest in the plant is held by the Icelandic State, and Johns-Manville Corp. of New York owns most of the balance. Almost all heat energy used at the plant comes from geothermal steam.

MINERAL FUELS

In 1977, hydroelectric and geothermal power continued to supply almost one-half of Iceland's energy needs. The remainder was supplied by imported petroleum products, mainly from the U.S.S.R. with some from Portugal and the United States. Iceland's supply and consumption of fuel and power in 1976 and 1977 is shown in table 4.

Geothermal Energy.—Repairs to the Krafla geothermal power station in North Iceland, damaged in a volcanic eruption, were to be completed in 1978. Funds for drilling new steam wells necessary to bring the plant to full power had not yet been allocated.

Owing to its location on the mid-Atlantic Ridge, Iceland has a very large geothermal potential, estimated at 3,200 megawatts.[4] At present, about 315 megawatts are used, mostly for space heating in the Reykjavik area and at Namafjall in the northeast.

Hydroelectric Power.—A 50-megawatt section of the 150-megawatt Sigalda hydroelectric plant started operation in 1977. The plant, located 130 kilometers east of Reykjavik, is owned and operated jointly by the Icelandic State and the city of Reykjavik.

Preparations for the Hrauneyjafoss hydroelectric project in southern Iceland, about 160 kilometers east of Reykjavik, continued, with bids being received for the 140-megawatt project.

At year end, installed hydroelectric capacity of the country was estimated at 600 megawatts-electric.

The Mineral Industry of India

By Gordon L. Kinney[1] and Francis E. Shafer[2]

In March 1977, India held a general election in which the Congress Party was ousted for the first time since the country became independent in 1947 and Morarji Dasai replaced Indira Gandhi as prime minister. The new Janata (People's) Party pledged to stimulate the growth of rural areas and encourage cottage and small-scale industry at the apparent expense of the heavy industry sector. How this change would affect the mineral industry in India was not clear at yearend.

The mineral industry accounted for only about 1.4% of India's gross national product (GNP) but was an important sector of the economy and employed about 4% of the organized labor force in 1977. Employment that depended directly on domestic mineral output, however, was several times that figure; sectors that depend on mineral output included steel, aluminum, copper, and zinc production and associated heavy manufacturing, transportation, and rural power development.

India has large reserves of coal, iron ore, bauxite, barite, mica, manganese, chromite, and heavy mineral sands, and was a substantial exporter of iron ore, manganese, mica, and chromite. Oil and natural gas output showed a marked increase compared with that of the previous year.

There were about 3,600 working mines, of which 880 were mechanized and produced 85% of the value of the total mineral production. India's per capita consumption of minerals was very low, about 1% that of the United States.

The Geological Survey of India (GSI), Mineral Exploration Corp. (MEC), National Mineral Development Corp. (NMDC), the various state mineral development corporations, Oil and Natural Gas Commission (ONGC), and other Government groups were all pursuing active programs of exploration and development of the country's mineral resources. The most important developments were confirmation of very large deposits of high-grade bauxite near the east coast and the development of the Bombay High oil and natural gas fields off the Indian west coast.

The Government's 1978-83 draft plan provided for over $4 billion for the nonfuel-mineral-related sector, a 30% increase over the figure in the previous plan period. About 72% of the expenditures were earmarked for the steel sector, 16% for iron ore, and 12% for the nonferrous metals. The major objective of the plan was to complete ongoing projects, but funds also have been programed for establishing two alumina plants on the east coast and expanding the country's steelmaking capacity. The plan also included an export target of 40 million tons per year of iron ore by the end of FY 1982. Where resources are not abundant, the Government Planning Commission recommended importing more ore, utilizing low-grade deposits to a greater degree, and limiting production to actual domestic needs.

India's petroleum production increased during 1977, but consumption increased even faster, causing imports to rise accordingly. Metallic and nonmetallic mineral production dropped slightly in value from the previous year due primarily to a slowing of industrial growth caused, in part, by power shortages and labor problems. Coal production remained static despite planned increases. Output was affected by power shortages, poor industrial relations, rail bottlenecks, and a shortage of explosives. As a result, coal shortages developed, affecting industrial consumers and further aggravating the electric power shortages.

The Indian economy in 1977[3] showed a growth of 7%. In current prices, India's GNP was $100.85 billion[4] in 1977 or $60.4 billion at constant 1970 prices. India's agri-

Digitized by Google

cultural sector accounted for nearly 45% of the GNP and was, therefore, a key factor in the economy. Growth during the year was due mainly to a very favorable summer monsoon season, which produced record crops, including a total foodgrain harvest of over 125 million tons.[5] The Government places a high priority on agriculture in the 1978-82 5-year plan. According to figures, 43% of development funds in the draft plan were to be spent on agriculture and related supporting activities. Irrigation and flood control projects were to be emphasized, thus lowering the country's strong dependence on a favorable monsoon season for the production of adequate food crops. The plan called for the irrigation of an additional 36 million acres during the 5 years, bringing the total to nearly 150 million acres. Other priorities included the doubling of nitrogen fertilizer production and the expansion of rural electrification to an additional 100,000 villages and 2 million electric water pumps.

Despite the recent gain in agricultural production, major problems continue to afflict the rural countryside. Growing population pressures (growth rate was nearly 2.5% per year) have resulted in higher rates of rural unemployment and underemployment, a declining average size of farms, and deforestation and severe overgrazing, resulting in increased soil erosion. Water was often used inefficiently or was not available in many places. Government programs for distribution of surplus land to landless laborers, credit to the rural poor, and food for work projects were proving very difficult to implement effectively.

The industrial sector showed a rather unsatisfactory 3.4% growth during 1977 compared with the 10.4% growth in 1976. The reasons were varied, but perhaps the underlying problem was an insufficient demand for many consumer goods, caused by over 50% of the population living below the poverty level. Other reasons were depressed investments in new projects owing to considerable underutilized capacity, fear of possible nationalizations, labor unrest, rail and water transport bottlenecks, and increasingly serious power shortages.

The chronic shortage of electric power continued to be a major problem facing the Indian economy. There was a 7-billion-kilowatt-hour shortfall between supply and demand during 1977. Shortages occurred in about one-half of the States during the year, with power cuts ranging from 5% to 55% for industrial consumers. The most affected industries were aluminum, iron and steel, cement, and petrochemicals. Even the agricultural sector was beginning to be affected, despite the fact that the Indian Government continued to give it priority whenever possible.

The Government's ambitious power-development plan called for an increase in the installed electrical capacity from 14,000 megawatts in 1970 to 45,000 megawatts by 1983. At yearend 1977, the installed capacity reportedly reached 25,180 megawatts as compared with 23,700 megawatts in 1976. Another 520 megawatts was tested but not fully commissioned. Despite the 6% increase in capacity, total power generated increased only 1% to 90 billion kilowatt-hours during 1977. This small percentage reflected breakdowns in thermal units due to obsolete equipment and poor maintenance, a low water level at the hydroelectric stations, and labor unrest. Between 1976 and 1977, the equipment and maintenance problems resulted in a 4% decline of the average-capacity-utilization factor.

The power shortages continued through yearend, and there was little chance of any significant improvement in the short term. Shortages and cutoffs in some of the major urban centers may very well increase in both magnitude and duration before the overall situation begins to improve.

PRODUCTION

The mineral industry of India contributed about $1.46 billion to the economy in 1977 or about 1.4% of the GNP. This was a decline of about 1% compared with the 1976 production value. Solid fuels contributed about 58% of the total value followed by petroleum and natural gas with 20%, metallic minerals with 14%, and nonmetallics with 8%. Iron ore furnished about 50% of the value of metallic minerals, followed by copper ore with 13%, manganese and chromium ores with 10% each, gold ores with 8%, and zinc with 5%. Limestone accounted for about 50% of the value of the nonmetallics, followed by phosphorite with 18%, dolomite with 5%, and magnesite with 4%.

Mining and quarrying employed an average of 762,000 persons in the public sector and 123,000 persons in the private sector during 1977.[6] This was roughly 4% of the total organized[7] employment of major industries and services.

Digitized by Google

Bihar was the leading producer among States, accounting for about 29% of the total value of mineral production in 1977, followed by Madhya Pradesh and West Bengal with 14% each, Gujarat with 12%, Assam with 10%, and Andhra Pradesh and Orissa with 5% each. Nearly all of Gujarat's and Assam's values were from petroleum and natural gas, while Bihar produced mostly coal, iron ore, copper ore, and bauxite.

Marginal production gains were recorded by copper ore, graphite, gypsum, lead and zinc concentrates, and phosphate rock, but output levels of apatite, chromite, mica, dolomite, iron ore, limestone, manganese, and pyrites were down. The iron ore decline was due mainly to the recession in the international steel market rather than from a lack of production capability.

In terms of metal output, both zinc and lead increased by over one-third, but plants continued to operate far below capacity. Total crude steel output increased slightly to over 9.9 million tons. Aluminum production, suffering most from power interruptions, declined 13%, and blister copper was off nearly 5%. In view of the continuing electric power and labor problems, the 1978 outlook appeared even less promising than 1977. Higher imports were anticipated to meet production shortfalls.

The Planning Commission projected sizable supply-demand gaps of over 70,000 tons of aluminum, 40,000 tons of copper, 55,000 tons of zinc, and 45,000 tons of lead by FY 1982. If these gaps are realized, it would be a serious blow to India's balance-of-trade situation and its economy in general.

[e]Estimate. [p]Preliminary. [r]Revised. NA Not available.

[1]In addition to the commodities listed, bromine, other clays (bentonite, fuller's earth, and common), other gem stones (aquamarine, ruby, and spinel), and uranium are also produced, but production is not reported and available information is inadequate for formulation of reliable estimates of output levels. In 1975, production of 6,514 metric tons of uranium ore containing about 3 metric tons of U_3O_8 was reported from two mines, but this output was only a part of total national production.

[2]Data are for calendar years; data for fiscal years beginning April 1 of years stated are as follows, in thousand metric tons: 1975—8,340; 1976—10,022.

[3]Data are for calendar years; data for fiscal years beginning April 1 of years stated are as follows, in thousand metric tons: 1975—7,186; 1976—7,910; 1977—9,670.

[4]Data are for fiscal years beginning April 1 of years stated.

[5]Data from the Fertilizer Association of India, Fertilizer Statistics, 1977-78, New Delhi, 1978, pp. I/37-I/39 and I/178-I/179; figures presented are for years beginning April 1 of that stated.

[6]Includes ammonium sulfate, ammonium sulfate-nitrate, urea, calcium ammonium nitrate, and ammonium chloride.

[7]Includes single superphosphate, pelophos, and triple superphosphate.

[8]Includes all reported varieties of nitrogenous-phosphatic and nitrogenous-phosphatic-potassic (NP and NPK) mixed fertilizers.

[9]Includes reinjected gas.

TRADE

India's world trade had a total value of $13.46 billion in 1977, an increase of nearly 12% over that of 1976. The figure represented over 13% of the country's GNP. After a modest, positive balance of trade in 1976, imports surged ahead of exports and at yearend 1977, there was a negative trade balance of over $800 million.[s]

Total exports were valued at $6.32 billion and included gems and jewelry ($470 million), iron ore ($295 million), steel ($268 million), base metals ($153 million), and silver ($100 million). Chromite, manganese ore, and mica were also important exports during 1977.

The total value of imports was $7.14 billion, a nearly 20% increase over that of 1976. The imports of raw materials, essential commodities, and capital goods will continue to rise and could result in a significantly larger trade deficit in 1978.

Mineral imports were dominated by petroleum in 1977 as they have been in recent years. Despite a 17% increase in domestic production, India's bill for nearly 15 million tons of imported crude oil was $1.5 billion, and for 2.7 million tons of refined products, an additional $340 million. Iran and Iraq supplied about two-thirds of the total crude oil imports, and the U.S.S.R. supplied most of the refined products.

India's major nonfuel minerals imports were uncut diamonds, specialty steels, lead and zinc concentrates, rock phosphate, and sulfur.

COMMODITY REVIEW

METALS

Bauxite, Alumina, and Aluminum.—Bauxite production, strongly dependent on the slumping aluminum industry, was basically unchanged from the previous year and totaled 1.5 million tons valued at $4.8 million in 1977. Nearly 90% of the production came from the States of Bihar, Madhya Pradesh, Maharashtra, and Gujarat. This pattern could change radically, however, in the early 1980's because of recent discoveries of rich bauxite deposits along the Andhra Pradesh and Orissa coasts.[9]

Based on the exploration by the Mineral Exploration Corp. (MEC) and the GSI, the east coast deposits were estimated to be some of the world's largest, about 1,250 million tons in Orissa and 750 million in Andhra Pradesh, based on cutoff grade of 40% Al_2O_3 and less than 5% SiO_2. About 700 million tons was already classed as proven. The bauxite is well suited for metallurgical use, being low in silica and titanium and high in gibbsite.

Reserves in the other States remain unchanged at about 400 million tons, bringing the country's total to about 2,400 million tons. India ranked fourth in the world in bauxite reserves.

Domestic consumption of bauxite during 1977 was just over 1 million tons, a slight decrease from that of 1976. In view of the continuing electric power shortage, production and consumption may be expected to increase only a small amount during 1978. Other bauxite consumers were the chemical, refractory, abrasive, cement, and steel industries.

A small amount of bauxite was exported to Spain and Abu Dhabi. According to the Government's current policy, low-grade bauxite was freely exportable but only limited amounts of high-grade bauxite exports (more than 50% Al_2O_3 and less than 5% SiO_2) were permitted. With development of the east coast deposits, this policy will no doubt be modified.

The major highlight in the alumina sector during 1977 was India's commissioning of two feasibility studies for establishing export-oriented alumina plants based on the rich, east coast bauxite discoveries.

An agreement with Pechiney Ugine Kuhlmann (PUK) of France called for an economic feasibility study for establishing a bauxite mine, a 600,000- to 800,000-ton-per-year alumina plant, a 160,000-ton-per-year smelter, a caustic soda plant, and downstream chlorine utilization facilities. Tentative location would be in Koraput district in southern Orissa State. Costs were estimated at $1.5 billion and would climb another $350

Digitized by Google

million with the construction of a 300-megawatt-capacity powerplant to support the smelter operation. Subject to Government approval of its feasibility study and arrangement of external financing, the first alumina could be produced during 1983.

The Soviets were also beginning a feasibility study for a 600,000-ton-per-year alumina plant based on the Andhra Pradesh deposits. Estimated cost of this project was $470 million. The Soviets would import between 300,000 and 400,000 tons per year, leaving the balance for sale to other countries. There were no plans to convert alumina from this project into aluminum. The final studies were expected by March 1979.

The Government signed an agreement with Hungary to set up a 300,000-ton-per-year alumina plant in Kutch district in Gujarat.

The State-owned Bharat Aluminum Co. Ltd. (BALCO) was the only company producing bauxite for both export and local consumption. However, the private company Indian Aluminum Co. Ltd. (INDAL) planned to expand its production at the Belgaum plant in Karnataka by 140,000 tons per year of alumina to feed Iran's Irak smelter, which was being expanded. The plans were not firm, but INDAL's relatively low costs and proximity to Iran appear to give the company an export advantage.

The severe electric power shortages during the year probably affected the aluminum industry more than any other mineral-related sector.

The electric-power-intensive aluminum smelters were consistently the plants subject to power cutbacks and outages. As a result, production declined sharply to 184,000 tons in 1977 from a record high of 212,000 tons in 1976. The installed capacity of India's five aluminum companies was over 275,000 tons per year, but utilization averaged only 67% during the year.

Aluminum metal production and yearend capacity, by plant, in tons, and utilization rate, in percent, in 1977 were as follows:

Company and plant location	Capacity	Production	Utilization rate
Private sector:			
Aluminium Corp. of India:			
Asansol, West Bengal	9,000	[1]	--
Hindustan Aluminium Corp. Ltd:			
Renukoot, Uttar Pradesh	100,000	73,119	77.0
Indian Aluminium Co.:			
Alwaye, Kerala	15,850		
Belgaum, Karnataka	60,000	65,609	68.2
Hirakud, Orissa	20,320		
Madras Aluminium Corp. Ltd.:			
Mettur, Tamil Nadu	25,000	16,745	67.0
Public sector:			
Bharat Aluminium Corp., Ltd.:			
Korba, Madhya Pradesh	50,000	28,381	56.8
Total	280,170	183,854	66.8

[1]Metal production ceased in September 1973.

Reportedly, the Government was considering the nationalization of Hindustan Aluminium Corp. Ltd. (HINDALCO), based on the recommendations of the Uttar Pradesh State government. Kaiser Aluminum and Chemical Corp. had a 27% ownership in HINDALCO, and the remainder was held by Birla and other Indian interests.

During 1977, BALCO finally commissioned its second 25,000-ton-per-year potline, bringing its total to 50,000 tons per year. The commissioning of a third potline of equal capacity awaited availability of electric power, and construction on a fourth potline neared completion at yearend. BALCO's FY 1978 production target of 74,000 tons did not appear feasible in view of the power problems.

Development plans called for increasing total capacity by the 50,000 tons per year under construction by BALCO and 25,000 tons per year by HINDALCO, also awaiting commission when power is available. This would bring India's total capacity to 350,000 tons per year. These increases and the efficient use of existing smelters can be achieved only if the Government's plans to increase India's total power capacity from 25,000 to 45,000 megawatts are carried out on schedule. Power projects have frequently missed planned startup dates in the past.

In order to meet the aluminum shortfall of about 16,000 tons in 1977, about 5,000 tons was imported at a cost of $4.9 million. The balance was made up from secondary metal. Imports, however, were likely to increase to about 20,000 tons in 1978.

Chromium.[10]—India's chromite produc-

Digitized by Google

tion was over 350,000 tons valued at nearly $20 million in 1977, down from 402,000 tons valued at $23 million in 1976. The decline was largely attributed to an inadequate domestic demand and the worldwide recession in the steel industry. Nearly 97% of the production came from Orissa.

Nearly 80% of the consumption is accounted for by the metallurgical and refractory industry, and 20%, by the chemical industry. Demand was estimated at 120,000 tons. Based on the proposed steel development program, India's total consumption was expected to be 150,000 to 160,000 tons by FY 1982, which would leave a sizable surplus for possible export.

Exports were 278,000 tons in 1976 valued at $31 million and were reported to be 117,000 tons for 1977. The depressed nature of the international market for chromite, particularly the reduced imports by Japan, has been a major factor affecting sales abroad.

Concerned about India's limited reserves, the Government banned the export of high-grade chromite, and exports of lower grades are subject to a quota system. A graded duty was recently imposed as a further step to conserve these resources.

Imports, the only source of chromium metal, amounted to 61 tons valued at over $400,000 in 1977. Since there were no plans for the domestic production of this metal, imports were expected to continue indefinitely.

Chromite reserves were officially put at over 17 million tons of all classes, with Orissa accounting for nearly three-fourths of the total. Exploratory work was underway by GSI to establish additional reserves. Exploration at Byrapur, Hassan district, Karnataka, indicated considerable potential for increasing the reserves. Based on preliminary results, the country's total reserves could be as high as 50 million tons.

Copper.—The Government-owned Hindustan Copper Ltd. (HCL) was organized in 1967 and charged with the responsibility of developing and exploiting the copper deposits in India and minimizing the country's dependence on foreign sources. HCL was given sole control of the copper industry when the privately owned Indian Copper Corp. Ltd. was taken over and incorporated into HCL in 1972.

The HCL mines in Rajasthan and Bihar continued to account for the major share of India's copper ore production; a small share came from Karnataka. Nearly 2.6 million tons were mined during 1977, over 7% more than in the previous year. The principal producing mines were Rakha Mosoboni, Pathargora, Surda, and Kendadih in Bihar; and Khetri, Kolihan, Chandmari, and Dariba in Rajasthan.

The ore production capacity at Khetri was designed for 3,000 tons per day, but production was actually averaging about 2,500 tons per day. This was to be stepped up to 4,000 tons per day by fiscal 1980. Kolihan mine production was about 1,600 tons per day and was to be increased to 2,000 tons per day. Chandmari, the only open pit operation at Khetri complex, produced about 500 tons per day and was scheduled for doubling to 1,000 tons per day by around FY 1981. The small Dariba mine produced about 100 tons per day. It will be difficult to attain the goals for ore production in view of the yearend FY 1977 labor problems and the continuing electric power shortages.

India's entire copper production came from HCL's two smelters, which have a combined capacity of 57,000 tons per day. They were located at Ghatsila in Bihar and Khetri in Rajasthan and supplied about 42% of India's annual requirements of 55,000 tons of primary copper.

Production of blister copper totaled about 23,500 tons, down marginally from 1976. Steps were underway to increase production to over 32,000 tons in FY 1978. However, there were labor problems at the Khetri complex that were unresolved at the end of FY 1977, and the electric power shortages in Bihar and Rajasthan were particularly acute. It was, therefore, unlikely that 1978 would show a significant production increase and may in fact, show a decrease from the 1977 output.

Copper consumption in recent years varied between 50,000 and 60,000 tons, but was projected to increase to about 80,000 tons by FY 1982. Despite new copper developments being planned or underway, India's domestic production is not likely to exceed 50% of its requirements by the end of the 1978-83 plan period. The balance will be made up by imports.

Copper metal imports were off by nearly 50% to about 20,000 tons costing about $30 million in 1977. Major suppliers were Zambia, Canada, Belgium, and Zaire. In addition to the metal, about 13,000 tons of copper concentrate was also imported. Plans called for the import of at least 32,000 tons valued at about $89 million during FY 1978, but this figure could be much higher

Digitized by Google

due to the continuing production shortfalls resulting from power shortages and technical difficulties.

Estimated at about 370 million tons in 1977, India's copper ore reserves remained small by world standards. About 90% of the country's reserves are located in Bihar, Rajasthan and Madhya Pradesh. MEC confirmed 8.2 million tons of polymetallic ore at Ambamata in Gujarat and 1 million tons at Mailaram in Andhra Pradesh. A sizable deposit of copper has reportedly been located at Tosham and Khodana in Bhiwani district in Haryana. Ongoing, detailed geochemical investigations were to determine the extent and mineralogy of the deposit.

Development and exploration activities were continued by the Government in an effort to locate new reserves and increase ore production. The most important development during the year was the approval by the Government of the Malanjkhand project in Balaghat district of Madhya Pradesh. The detailed project report was made by Soviet mining experts. The open pit operation was expected to produce 1 million tons per year of ore by FY 1981 and 2 million tons by FY 1983. A mill at the mine was to produce 100,000 tons per year of 25% copper concentrate. The concentrate will be shipped to Khetri to utilize the idle capacity at the smelter. Development costs were planned at over $100 million and will probably rise considerably higher in light of rapid cost increases. HCL planned to appoint local contractors and avoid imports of equipment as far as possible for the construction job.

Other copper deposits were explored or were being drilled to determine reserve status. In Rajasthan they were at Singhana in Jhunjhunu district, Padarkipal in Dungarpur district, Derhi and Basantgarh in Sirohi district, and Khankhera in Bharatpur district. MEC began exploratory mining operations to further evaluate the Kesarpur copper deposit in the Mayurbhanj district in Orissa. GSI had earlier completed a detailed drilling program at the site. About 1.7 million tons of chalcopyrite ore with a 0.7% copper cutoff was proved. The average grade was reportedly 1.59% copper. If the deposit can be exploited economically, a mill will be built at the site and the concentrate shipped to the Ghatsila smelter.

Iron Ore.—Iron ore production declined slightly in 1977 mainly because of lower export demand, but India remained the seventh largest producer in the world. Despite the decline in tonnage, the mine value of the ore remained steady at about $102 million. This ranked iron third behind coal and petroleum in value for all Indian minerals produced.

Nearly 60% of production came from Madhya Pradesh, Orissa, and Bihar where most of the integrated steel mills are located. Goa produced around 30% of the total, mostly for the export market. Domestic consumption remained steady at about 18 million tons. The projection for 1978 was 18.9 million tons.

According to the Government's 1978-83 plan, iron ore production was to be increased from 43 million to 65 million tons by the end of FY 1982. Most of the increase was to come from the Kiriburu mines in Orissa, the new mines at Donimalai in Karanataka, which went into production in late 1977, and the Bailadila deposit No. 5 in Madhya Pradesh, which was commissioned in early 1977. The mines were being developed by the National Mineral Development Corp. (NMDC). Other major hematite areas under development by NMDC included the Bellary-Hospet region of Karnataka, which, in addition to the Donamali mines, included the Ramandurg and Kumaraswamy deposits; Rowghat and Dallirajhara of Madhya Pradesh; and the Meghahatuburu and Malangtoli deposits of Orissa. The Meghahatuburu deposit was being developed to produce 1.3 million tons of lump ore and 3 million tons of fines per year for the Bokaro steel plant. Work had begun on the mine, but there had been little progress on the processing plant by yearend.

NMDC was also conducting feasibility studies of Bailadila deposits 11C and 13, Kumaraswamy B and D ore blocks, and Kiriburu central ore block.

There were two, private-sector pelletization plants with a combined capacity of 1.5 million tons per year in operation, one in Goa and one at Noamundi in Bihar. A third plant, of 1.8 million tons per year capacity, was under construction in Goa. The plant was designed by the West German firm Lurgi and owned jointly by the Steel Authority of India, Ltd. (SHIL), and Chowgule & Co. Pvt. Ltd. The plant is scheduled to start operations in early 1979 and supply pellets to Japan under a 10- to 12-year contract beginning in 1980.

Exports for FY 1977 declined by 1.3 million tons to 21.8 million largely because of a

Digitized by Google

cutback of Japanese steel production. Although the volume declined, the value rose to $295 million from $280 million in 1976. Japan accounted for about three-fourths of the exports. The Minerals and Metals Trading Corp. (MMTC), which handled all exports except the Goa material, initiated steps to explore new markets. A trial shipment of 20,000 tons was made to Iraq. A contract for the supply of 20,000 to 30,000 tons was signed with the Peoples Republic of China. Negotiations were also going on with Pakistan, Bulgaria, and Romania for further export orders. The export target for FY 1982 was 40 million tons, including 7.5 million tons of magnetite concentrates to Iran from the Kudremukh project. Kudremukh will supply a total of 150 million tons of pellet feed over a 20-year period. Progress on the $630 million Kudremukh construction was about on schedule at year-end. Canadian Met-Chem Consultants Ltd., a subsidiary of United States Steel Corp., was the foreign consultant on the project. The firm was in charge of design, engineering, procurement, and supervision of construction, and also will manage the project for 3 years after completion.

India's iron ore reserves continued to increase as detailed exploration work progressed around the country. The total of all grades and types was estimated to be over 17 billion tons but may be a great deal higher. Proved reserves of hematite were over 6.6 billion tons of +62% iron ore. The Chiria deposit of 1.97 billion tons in Bihar was the largest hematite ore body in India.

The largest magnetite deposit was in the Bababudan hills of Karnataka where inferred reserves were 3 billion tons of banded magnetite-quartzite ore with a 30% iron content. Preliminary drilling indicated a workable ore body of 1.5 billion tons and very little overburden. The iron content of economic Indian hematite ranges from 62% to 65% compared with 26% to 35% for magnetite. India's iron ore resources, by State and type of ore, were as follows, in million tons of ore:

Type of ore and State	Measured	Indicated	Inferred	Total
Hematite:				
Bihar	2,635	80	509	3,224
Goa	100	119	192	411
Karnataka	518	208	492	1,218
Madhya Pradesh	1,439	1,044	553	3,036
Maharashtra	101	94	36	231
Orissa	1,825	361	823	3,009
Rajasthan	1	--	12	13
Total	6,619	1,906	2,617	11,142
Magnetite:				
Andhra Pradesh	--	--	105	105
Karnataka	610	--	4,554	5,164
Kerala	--	--	96	96
Tamil Nadu	107	--	539	646
Total	717	--	5,294	6,011
Grand total	7,336	1,906	7,911	17,153

Iron and Steel.—In contrast to the steel supply surplus of the past 3 years, India showed a short supply and a steady rise in the prices of steel by the end of FY 1977. A large expenditure on construction of various development projects in the past year spurred a 14% rise in domestic steel demand. However, crude steel production in three of the six integrated steel plants declined in FY 1977. Shortages of electric power and coal and labor unrest reduced the annual average rate of capacity utilization by the integrated mills to 89.5% from 1976's record level of 92%. Total crude steel production advanced only 1%, the smallest rate in 4 years. The increase in domestic demand and shortfalls in production in some of the mills eliminated the excess supply of steel. Steel shortages induced the Government to curb exports and relax some import controls in FY 1977. India, however, retained its previous year's position as a net exporter of steel. Prices rose between 10% and 30% during 1977, depending on the type of steel.

The Government, despite its bias for rural development, recognized the need for expansion of the indigenous steel production capacity. However, lack of funds and the increasing costs of new plants restricted rapid expansion of the steel industry.

Production.—Preliminary official esti-

Digitized by Google

mates show that India produced 9.8 million tons of steel ingots in FY 1977, a 1% increase over FY 1976. This was the smallest growth in the past 4 years and a sharp decrease from the record 23% growth rate of FY 1976. Similarly, total finished steel production in FY 1977 rose to 6.98 million tons from 6.90 million tons in 1976. Pig iron production declined 5% to 9.5 million tons, reversing the upward trend of 1976, when production increased 20%.[11]

The stagnation of steel production resulted from lost output at three of the public-sector plants—Bokaro, Rourkela, and Indian Iron and Steel Co. It was estimated that electric power shortages caused a direct loss of 100,000 tons of ingot production. Shortages and the poor quality of coking coal led to further production problems.

In contrast to the shortfalls of the public-sector plants, the Tata Iron and Steel Co., the oldest mill in India and the only privately owned, integrated mill in the country, produced 6% more than its rated installed capacity. The overall capacity utilization of the integrated mills dropped to 89.5% from the peak of 92%. In addition to the power and coal problems, labor troubles contributed to the lowered efficiency in industry. Coal stocks on hand at the mills decreased during the year, and by yearend, it appeared that some mills would suffer production losses in 1978 if the coal situation did not improve markedly.

The secondary producers and the steel minimills in the private sector also did well and increased crude steel production by 12% to 1.2 million tons in 1977. The shortages of the integrated plants will give the steel miniplants a chance to increase production further in 1978. Total capacity of the 400 miniplants was over 4 million tons per year, but only about 120 of the plants were operating during 1977, most of them at well below capacity. Average capacity utilization, however, increased from 44% in May 1977 to 60% by the end of FY 1977.

Official production targets for the integrated mills for FY 1978 called for a 16% increase in steel ingots and 10% increase in salable steel. The outlook, however, was not promising because power and coal shortages were continuing at yearend. The target for the steel minimills called for a substantial increase of over 30%. In January 1978, to encourage output, the Government permitted the electric furnace units to arrange direct, tariff-free imports of ferrous scrap, to a limit of 200,000 tons each. The successful increase in the steel minimills' production will depend very heavily on whether adequate electric power can be obtained and whether they are permitted to diversify their production from mild steel to alloy and special steels.

Exports and Imports.—With the rise in domestic demand, steel export earnings were down about one-third to $268 million from the sale of 1.8 million tons in FY 1977. Most of the steel went to the Middle East countries. Pig iron, bars and rods, billets, and structurals were the main items of export. Because of the substantial rise in the domestic demand, the export target for FY 1978 was revised downward to 800,000 tons valued at roughly $117 million. Even that figure may prove to be high, and a more realistic figure would be in the 500,000- to 600,000-ton range.

Steel imports were estimated at 350,000 tons valued at $139 million in FY 1977, a slight increase over that of 1976. Imports for FY 1978 were projected at 500,000 to 600,000 tons, consisting of cold-rolled sheets, plates, structurals, and tinplate. Steel imports were expected to continue for several years at about 500,000 tons annually, despite projected increases in production, because it was uneconomical to produce certain low-volume products. Also, certain highly specialized steels and alloys were not available domestically.

Development and Expansion.—The 1978-83 plan called for an increase in steel production from 9.8 million tons in FY 1977 to 15 million in FY 1982. The largest recipient of investment funds in the industry and minerals sector was steel, with an allocation of about $2.93 billion, mostly for ongoing projects. Increased investment costs and lack of funds restricted the rapid expansion of the steel industry. Major programs already approved were as follows:

The Bhilai Steel Plant was expanded from 2.5 million tons to 4 million tons to produce additional amounts of heavy plates and billets. The U.S.S.R. will supply continuous casting equipment for a 3.6-meter-heavy-plate mill complex. The overall expansion costs at Bhilai have inflated to at least $1.3 billion. Most of the new equipment was to be completed by December 1981, but the seventh blast furnace was scheduled for June 1983 commissioning.

Bokaro Steel Ltd. completed its first phase construction with assistance from the U.S.S.R. An annual capacity of 1.7 million tons of crude steel was achieved when

Digitized by Google

the first cold-rolling mill and the third blast furnace were commissioned in June 1977 and February 1978, respectively. The expansion from 1.7 million to 4.0 million tons per year by 1980 was underway at an investment cost inflated to $1.26 billion. The second cold-rolling mill alone was to cost $350 million. Metallurgical and Engineering Consultants (India) Ltd. and Engineering Projects India Ltd., both Government-owned, took over the expansion project at Bokaro from the U.S.S.R. and enlisted assistance and licensing from a U.S. firm for technology, design, and equipment.

The only major new plant in the 5-year plan was the Salem steel plant in Tamil Nadu. Construction of the 32,000-ton-per-year first phase began in 1977 at a cost of $150 million. The budget allocation for FY 1978 was about $12 million. After completion of the second phase of construction, the planned annual capacity was to be 70,000 tons of cold-rolled stainless steel, 75,000 tons of electrical steel, and 75,000 tons of low-alloy, special steels. Total cost was estimated at $660 million.

The Rourkela steel plant was installing a cold-rolling mill for completion in FY 1981 and also planned to modernize its 18-year-old hot strip mill.

The Durgapur plants were scheduled for modernization and expansion and the old Indian Iron and Steel Co. facility, a chronic money loser, was scheduled to be extensively rehabilitated by the replacement of badly out-of-date machinery and equipment.

Plans for three export-oriented coastal steel plants have progressed slowly because of the high costs involved. Negotiations, however, were continuing with the Soviets for the initial establishment of the first plant, a blast furnace at Visakhapatnam to produce pig iron for export to the U.S.S.R.

A 30,000-ton-per-year sponge iron demonstration plant, partially financed by the United Nations Development Program, was being constructed at Kothagudam in Andhra Pradesh at a cost of $13.5 million. The Lurgi Co. of the Federal Republic of Germany was providing the technical assistance and equipment. The Indian Government authorized the plant in an effort to develop a suitable, economical process for direct reduction of iron ore utilizing the country's abundant, high-ash, noncoking coal as the reductant.

Construction of a second sponge iron plant was also expected to begin soon, in northern Orissa. The plant will produce 150,000 tons per year and will be based on different technology and equipment supplied by Allis Chalmers Co. (United States). Estimated cost was $28 million.

Lead.—India's domestic demand for primary lead was roughly 50,000 tons per year and was expected to increase gradually to 60,000 tons by 1982 and 80,000 tons by 1987. Production was over 7,600 tons in 1977, valued at about $6 million at 1976 prices. That was an increase of more than 40% over the previous year. Output was targeted for a substantial increase in 1978 and a further increase to 15,000 in 1982. In the face of the shortage of about 45,000 tons per year, lead imports will continue.

Lead was smelted at the Hindustan Zinc Ltd.'s (HZL) 8,000-ton-per-year plant at Tundoo in Bihar. A second smelter was under construction at Visakhapatnam in Andhra Pradesh, which will have a 10,000 ton-per-year capacity at its scheduled completion in June 1979. The Tundoo plant was fed by concentrates produced at the HZL's Zawar mines in Rajasthan, and the Visakhapatnam smelter was to operate on imported concentrate.

Production of lead concentrates was estimated at 16,700 tons in 1977, up marginally from 1976. Nearly 90% of the production was from HZL's Zawar and the remainder from HCL's mines in Agnigundala in Andhra Pradesh. With further development of the lead-zinc mines in Rajasthan, the production of lead concentrates should improve significantly. Plans called for an increase in ore production from 100 tons per day to 240 tons per day at Agnigundala. A small concentrator at Agnigundala produced 70% lead concentrate, which was shipped to Tundoo for smelting.

During 1977, imports were estimated at over 51,000 tons compared with 46,000 in 1976 and more than 21,000 in 1975. Anticipating higher production in 1978, lead imports were projected at 40,000 tons valued at about $36 million.

Manganese.—India's manganese ore production remained about 1.8 million tons in 1977. Orissa, Karnataka, Madhya Pradesh, and Maharashtra accounted for nearly all of the production. The public-sector, Manganese Ore (India) Ltd., operated the majority of the high-grade deposits and produced over 75% of the country's high-grade ore and 25% of the total production.

The lower grades of manganese ore are used directly in the steel industry, while the higher grades were used for ferroman-

Digitized by Google

ganese production. Since 1971, the country's manganese ore consumption has almost doubled, reaching 826,000 tons in FY 1976. Because of the projected 50% increase in India's steel production during the current plan period, consumption of manganese ore was projected to rise to about 1.4 million tons by yearend 1982.

Since 1974, India's manganese exports have steadily declined, although the earnings have remained relatively stable due to price increases. Exports in 1977 were about 550,000 tons compared with 714,000 in 1976. In view of the anticipated rise in domestic requirements and limited reserves, an export ban was levied on high-grade ore and a ceiling on low-grade. A small amount of specially processed high-grade ore was imported for dry-cell production.

To eliminate the imports and better utilize the domestic reserves, a 1,000-ton-per-year electrolytic manganese dioxide plant began commercial production in 1977 in Trevandrum in southern Kerala. The process technology was developed by the National Metallurgical Laboratory at Jamshedpur.

There was some controversy as to the total reserves of manganese in India. The Indian Bureau of Mines reported 108 million tons of all grades. Other reports put the figure as low as 79 million tons. In any case, the Indian Government was concerned with the rapid depletion of the strategically vital and valuable mineral resource. The GSI recently reported a new discovery of up to 10 million tons in Bastar district of Madhya Pradesh.

To formulate a long-term policy for export and internal consumption, a detailed investigation of manganese resources was begun. The Government also initiated a program for the optimum utilization of manganese reserves through beneficiation of low-grade ores, dephosphorization of high phosphorous ore, and the use of fines and rejects.

Nickel.—India met the major share of its nickel requirements through imports from the United Kingdom, Australia, and Finland. Imports totaled over 5,500 tons valued at nearly $26 million, a 23% increase in tonnage over those of 1976. Demand was expected to increase during the early 1980's with the scheduled commissioning of the Salem special steel plant in Tamil Nadu.

The only domestic source was the copper smelter at Khetri where nickel sulfate was recovered as a byproduct. Recovery was about 150 tons in 1977, and the target for 1978 was 180 tons. Prospects for increasing the domestic byproduct recovery were good in view of the planned production increases for domestic copper.

The country's nickel ore reserves were put at about 100 million tons. About 69 million tons averaging 0.85% nickel was located in the Sukinda area of Cuttack district in Orissa. Based on a deposit averaging 1.1% nickel in the Kansa block of Cuttack, the Government proposed to set up a nickel plant at an estimated cost of $100 million. The project called for the production of 4,800 tons of nickel, 200 tons of cobalt, and 17,000 tons of byproduct ammonium sulfate fertilizer. The U.S.S.R. and Cuba offered to undertake a feasibility study concerning this Sukinda plant. Several foreign firms had earlier expressed interest in this deposit. The lateritic ore reportedly will be difficult and expensive to concentrate and refine, a problem which may jeopardize the economic viability of the project. About $1 million had already been spent on preliminary work and the FY 1978 budget provided a small allocation for the feasibility study. A new nickel deposit was identified during the year in the Mayurbhanj district of Orissa. Exploration drilling indicated over 17 million tons at a cutoff grade of 0.79% nickel.

Zinc.[12]—India relied primarily on imports to meet its domestic requirements for primary zinc metal, which are estimated at 100,000 tons in FY 1977. Major consumers were the Rourkela steel plant, the brass industry, die casting, and dry batteries. HZL met about 36% of the country's total demand in 1977 but was expected to increase its share to 50% in 1978 and to about 60% by 1982. Nevertheless, a sizable gap between supply and demand was expected to remain since consumption was expected to reach 130,000 tons by 1982 and 170,000 tons by 1987.

Imports in 1977 reportedly reached more than 63,000 tons compared with 1976 imports of 20,000 tons. A more liberal import policy and the high cost of Indian production compared with the world market price contributed to the large rise in imports. Zinc imports for 1978 were projected at 45,000 tons. Production and market conditions in 1977 indicated that India will continue to rely on imports of zinc metal and concentrates for an indefinite period.

Zinc production was confined to HZL's two smelters, one at Dariba in Rajasthan

Digitized by Google

(45,000 tons per year capacity) and the second at Visakhapatnam in Andhra Pradesh (30,000 tons per year capacity), plus the 20,000-ton-per-year, private-sector plant at Alwaye in Kerala, operated by Cominco Binani Zinc Ltd.

Domestic zinc production has climbed steadily since 1973 when production was 12,500 tons. It reached 36,000 tons in 1977, with an estimated value of $41 million. Although production was one-third higher than in 1976, it was still considerably below the total 95,000-ton smelter capacity. Production would have been higher at the Dariba plant but electric power shortages caused an estimated 15% loss of production in 1977. HZL plans called for raising zinc production to 62,000 tons in FY 1978, and 75,000 tons by FY 1982.

Both the Visakhapatnam and Kerala plants operated on imported concentrates. As additional zinc mines come into production in Rajasthan, the Visak plant will begin to use domestic concentrates. In 1977, the Dariba smelter depended on ore supplied by the nearby Mochia and Balaria mines of the Zawar group in Rajasthan. Production of zinc concentrate in 1977 amounted to 46,000 tons, marginally higher than in 1976.

Ore production rose nearly 15% to 916,000 tons in 1977, possibly indicating some reduction in ore grade reaching the concentrator or stockpiling at the mine site. Average ore grade was reported to run 3.4% zinc and 1.2% lead. Projected ore production in FY 1978 was 1,180,000 tons.

Development of the Rajpura-Dariba mine with a planned 3,000-ton-per-day capacity was continuing. The main shaft reached the 100-meter level during 1977. The final depth was to be 550 meters, and the mine production was scheduled to yield 40,000 tons per year of zinc content, 13,000 tons of lead content, and about 13,000 kilograms of by-product silver. Two other mine developments were called for by FY 1984 to feed HZL's smelters. These were the Zawarmala mines, which were being designed for an annual ore production of 450,000 tons by FY 1982, and the Baroi mine was expected to reach the same output by FY 1984. HZL claimed that completion of these mines would eliminate the need to use imported concentrates at the Visalkhapatnam smelter.

India's zinc and lead reserves of all classes were estimated at 121 million tons, of which nearly 97 million was located at the Zawar group of mines and the Rajpura-Dariba belt of Rajasthan. Proved ore in the Zawar group was 21 million tons grading 4.2% zinc and 1.8% lead. The remaining reserves were located at Agnigundala in Andhra Pradesh (12 million tons), Ambamata in Gujarat (7 million tons), and Sargipalli in Orissa (5 million tons). Reportedly, a new lead-zinc deposit of 4 million tons of 10% combined metal content was discovered at Gorubathan in Darjeeling, district of West Bengal.

NONMETALS

Barite.—India ranked third in world production of barite, valued at the mine at nearly $2 million in 1977, about 25% more than in 1976. India's reported barite reserves in the proved category were the highest in the world.

Since domestic consumption was only about 80,000 tons per year, barite has become a major export commodity, exceeding 190,000 tons in FY 1977 valued at $14 million.[13] Although there was a decline in export tonnage in 1976, the value of foreign sales have increased each year since 1973. The principal importers were the Persian Gulf countries. Since January 1976, barite exports were channeled through the Government-owned MMTC. However, according to a new policy, the Government will permit exports through both MMTC and private exporters. A ceiling of 200,000 tons total annual exports continued, presumably with an aim to regulate foreign sales in order to realize a high unit value. Prospects continued promising in view of the country's large reserves and India's proximity to the Middle East market. Steps were underway to establish additional pulverizing units to process barite for export.

Cement and Limestone.—Although of low unit value, limestone accounted for nearly one-half of the total value of India's nonmetal mineral production during 1977. The cement and iron and steel industries were the major consumers of limestone. With the projected step-up in output of cement and steel to 30 million tons and 15 million tons, respectively, by FY 1982, total limestone consumption was expected to be around 50 million tons by the end of that year. A large deposit of metallurgical-grade limestone at Bilaspur was under development by the management of the Rourkela steel plant. Reserves at the site, which covers 10 square kilometers to a depth of 40 meters, were sufficient for several centuries of operations.

Digitized by Google

Demand for cement continued to exceed production by nearly 2 million tons, despite a small increase in output during 1977. Overall capacity utilization of 55 units averaged about 87%. Power shortages were the major constraint to a higher output. An additional demand for cement for reconstruction purposes resulted from two severe cyclones that hit southern India.

According to the 1978-83 plan, cement production was expected to increase from 19 million to 30 million tons by the end of FY 1982. However, even operating at full capacity, imports of 1 million to 2 million tons may still be necessary. The public-sector Cement Corp. of India (CCIO) planned to establish five new cement plants with a total capacity of 2 million tons per year as part of the plan's development program.

Prompted by Government fiscal incentives and the prospects of higher demand, several private-sector companies have applied for licenses to set up new plants. Larsen & Toubro Co. planned to invest more than $115 million in a plant to be set up in two stages of 2,500 tons per day each. The plant would be located in Chandrapur district of Maharashtra. The Steel Ministry also planned to set up cement plants of 1 million tons per year capacity each at the Rourkela and Bhilai steel mills. Cement clinker was to be mixed with equal volumes of granulated slag available as waste at the two plants. Chowgule & Co. Pvt. Ltd. planned to set up a 1-million-ton-per-year cement plant at Jafrabad in Gujarat and two clinker grinding plants, one at Surat and one at Ratnagiri.

Because of the domestic shortages during 1977, cement exports were restricted to about one-quarter of the original target of 1.5 million tons. Imports during FY 1977 were over 333,000 tons from the Republic of Korea, Romania, and Poland, out of the contracted 840,000 tons. The remaining tonnage was to be delivered during FY 1978. Trade sources indicated that annual imports of 1 million to 2 million tons would be required for several years in view of the continuing shortages.

Diamond.—Domestic production of rough diamond was entirely from the Government-owned Panna Diamond Mines in Madhya Pradesh, operated by MMDC. During 1977, these mines yielded industrial and gem-quality diamonds worth about $1 million, a little less than in 1976. Plans called for the expansion of these mines with Soviet assistance.

India's small native production of diamond belies the importance of the industry in the economy of the country. India was one of the world's major cutters and polishers of gem diamond, particularly the very small stones.

Exports of diamond, including jewelry, were estimated to have increased more than 50% to a record high of at least $470 million in FY 1977; and diamond ranked fourth among India's exports. Cut and polished diamond accounted for over 80%, and other gem stones most of the remaining amount. Belgium emerged as the leading buyer, displacing the United States which held that position in FY 1976.[14] Exports to Belgium more than doubled and exports to the United States nearly doubled over the 1976 levels. Other major importers of Indian stones and jewelry included Hong Kong, Japan, the Netherlands, the Federal Republic of Germany, France, and the United Kingdom.

India's diamond industry was obviously dependent on the import of rough diamonds. These imports rose substantially to about $270 million in FY 1977. In view of the high export demand for finished stones, the import bill for FY 1978 could reach as high as $400 million. The United Kingdom and Belgium were the major sources of these stones. To improve India's competitiveness in the world market, the Government abolished the 50% import duty on rough diamonds. In addition, import policies regarding machinery and equipment required by the gem and jewelry industry were liberalized.

India's diamond industry was mainly concentrated in Gujarat with nearly 65% of diamond cutting and polishing being carried out in the city of Surat. Jaipur in Rajasthan was another important gem center. The industry employed about 200,000 persons during 1977.

Fertilizer Materials.—The Fertilizer Corp. of India (FCI), the Government-owned fertilizer producer, was reorganized into four separate companies, operating on a regional basis. The reorganization was designed to overcome the problems created by FCI's unwieldy structure. The four companies were National Fertilizers Ltd., Rashtriya Chemicals and Fertilizers Ltd., Hindustan Fertilizer Corp. Ltd., and the original parent company, FCI. The old Planning and Development Division of FCI at Sindri became a separate entity called Fertilizer (Planning and Development) India

Digitized by Google

Limited (FPDIL). FPDIL will be the major consultant organization in the field of fertilizers and chemicals.

Total plant nutrient consumption (N, P_2O_5, and K_2O) increased over 25% in 1977 to nearly 4.3 million tons. India produced about 65% of its total needs and was forced to import the remainder at a cost of $360 million.[15] There was no production of potassium minerals for agricultural use, forcing India into total dependency on foreign supplies. The largest jump in production was in phosphate fertilizers, which rose over 40% in 1977 and more than doubled since 1975. No new production capacity came onstream during 1977, and the production increase was entirely due to better performance of existing units. Overall production in the fertilizer industry was restricted by electric power, labor, and maintenance problems.

Phosphate rock production rose to a record high in 1977. Nearly 92% of production came from India's largest deposit at Jhamarkotra near Udaipur in Rajasthan. More than 50% of the country's proved reserves were in this one deposit. Only the highest grade ore was extracted during 1977 and processed into phosphoric acid and superphosphate fertilizer. However, following detailed evaluation of the ore, it was decided that Rajasthan State Mines and Minerals Ltd. would set up a beneficiation plant at Jhamarkotra. The plant would process 1.5 to 2.0 million tons per year of ore and produce 0.75 to 1.0 million tons of marketable concentrate. The only phosphate rock concentration plant in the country, located at the nearby Maton mine, apparently doubled its capacity to 600 tons per day in 1977. The concentrate was consumed locally at HZL's byproduct fertilizer plant.

In an effort to find domestic supplies of potash, the GSI continued drilling in 1977 in the Nagaur Basin of western Rajasthan. Potash-bearing minerals were detected during the year in a 104-meter-thick halite bed at Lakhasar, Churu district. As a result, the exploration was to be intensified during 1978 by deploying two or three additional drills to test the gravity lows delineated by earlier geophysical surveys.[16]

The 1978-83 plan called for increases in nitrogeneous and phosphatic fertilizer production to 4.1 million tons and 1.1 million tons, respectively, by the end of the period. By then, estimated nitrogen (N) consumption was expected to reach 5.25 million tons, and P_2O_5 consumption, 1.6 million tons. The supply-demand gap must be filled by the continued import of costly fertilizers. Plants under construction or in final stages of planning in 1977 were to expand ammonia capacity in India by almost 2.8 million tons per year N, urea capacity by 2.2 million tons per year N, and complex fertilizer capacity by 500,000 tons per year. In addition, 180,000 tons per year P_2O_5 phosphoric acid capacity and 156,000 tons per year P_2O_5 triple superphosphate capacity was due to be commissioned in the near future.

The Indian Government abandoned plans for the construction of a large ammonia-urea complex at Mathura in Uttar Pradesh.[17] Review of the plans indicated that pollution from the proposed plant could have adverse effects on the historical monuments at nearby Agra. The lost capacity from the plants' cancellation will be made up by two new large fertilizer projects to be built in the Bombay area using offshore natural gas as feedstock.

Mica.—India's mica production continued a downward trend for the seventh consecutive year. The value at the mine was $2.6 million in 1977, a 2% decline from that of the previous year. Almost all of the production came from Bihar, Andhra Pradesh, and Rajasthan. Despite the drop in production, India accounted for nearly 70% of the sheet mica produced in the world.

The great majority of mica was graded, sorted, and split, and then exported at a considerable increase in value. Total value of exports in 1977 was about $29 million, with blocks and splittings, less than one-quarter of the total tonnage, accounting for about 83% of the sales value. The U.S.S.R. imported about 30% of the Indian mica, with the United States, United Kingdom, Federal Republic of Germany, Japan, and Poland accounting for most of the remainder.

To boost the export value of mica, the Government established a committee to prepare a program for the development of mica-based industries. Since fabricated mica brings a significantly higher value than the processed mica, the Government was seeking to develop indigenous expertise in this sector. The Government's Mica Trading Corp. planned to set up a series of plants to produce mica capacitors, wet-ground and micronized mica powder, and mica paper. The German Democratic Republic was asked to prepare a feasibility report for a mica paper plant for domestic consumption

Digitized by Google

and export. Negotiations were also underway with a U.S. firm for setting up a micronized mica powder plant.

The Indian Bureau of Mines located a new mica pegmatite mine in Mellore district of Andhra Pradesh. Reserves at the site were not determined. A second pegmatite ore body was indentified nearby.

MINERAL FUELS

Coal.—Coal continued as the principal source of commercial energy in India. The country's vast coal reserves were officially estimated at 84 billion tons. Production, however, remained static for the second year in a row, and the outlook for any significant increase in 1978 was not encouraging. Failure to increase production was due mainly to labor problems and shortages of electric power and explosives.[18]

Despite the impressive reserve figures, only about 25% fell in the proved category and most of this coal was of inferior grade with an ash content of 17% to 50%. Most of the coal is quite low in sulfur content, which is an advantage, but even the relatively small amount considered of coking quality is of such high ash content that serious problems in the steel industry could result.

India's coal industry faced a number of problems including surplus labor and a high rate of absenteeism, which affected cost and productivity. Coal India Ltd. (CIL), the Government-owned holding company for the coal industry, employed nearly 500,000 people, roughly 55% of the total mineral industry labor force. The surplus labor force totaled about 50,000. CIL was seeking to raise coal output by introducing sophisticated mining technology and equipment, but this contradicted the Government's policy of promoting more employment through the use of more labor rather than more capital equipment. At the same time, labor problems plagued the industry with over 490,000 employee-days lost in 1977, compared with 370,000 in 1975. Absenteeism in the coal sector averaged about 20% during 1977.[19]

Another major problem was the inadequate coal prices which have remained unchanged since 1975. According to CIL, the industry loses $1.18 on every ton of coal produced. Although a price hike was under consideration by the Government, it is likely that any raise granted would be offset by an increase in wages.

Other problems included increasing ash content in both coking and noncoking coal, shortages of railway cars, and inefficient operation of the coal washeries.

The 1978-83 Government plan called for an expenditure of over $2 billion to increase coal production by over 46 million tons per year by FY 1982. This was a considerable increase over the former 5-year plan but less than 3% of the total public-sector outlay for the period.

The plan stressed the need for short construction period projects and full-capacity utilization of existing mines. Emphasis will be on reconstruction and consolidation of existing mines and adoption of new mining technology with a stress on open pit mining. Roughly 60% of CIL's additional production was expected to come from open pit operations. One of CIL's affiliates, Eastern Coalfields Ltd. (ECL), planned to open 18 new mines and reorganize 28 existing mines by FY 1982. Of the new mines, nine are to be in Raniganj field, one at Bankura, six at Muguma, and two at Rajmahal. The ECL mines had special significance because the Raniganj mines produced some of the best metallurgical coal in India.

Lignite.—Total production in 1977 declined because of unusually heavy rains and a 16-day strike at the open pit workings, and the mine head value fell correspondingly $3 million to nearly $20 million. Nearly all of the lignite production came from the Neyveli complex in Tamil Nadu.

The lignite was used as the primary energy source for electric power generation in Tamil Nadu, which had no oil, natural gas, or coal deposits. Carbonized briquettes for domestic fuel and fertilizer were also produced at the complex.

Plans called for the expansion of production to 6.5 million tons annually by FY 1980, mainly through the purchase of additional earth-moving equipment estimated to cost about $150 million. The Government also approved the opening of a second mine cut with a capacity of 4.7 million tons annually and the installation of a 630-megawatt power station at the new mine. Cost of opening the second pit and powerplant was estimated at $440 million.

Petroleum.—The Indian Government reorganized the Oil and Natural Gas Commission (ONGC) at yearend 1977. Three new members were added giving a wider Government coverage to the membership. In addition, the onshore, offshore, and foreign activities of the ONGC now will be administered separately by executive directors with complete administrative control over their respective operations, subject to review of the ONGC. The changes should

Digitized by Google

expedite the decisionmaking process and strengthen management control over the industry.

Total crude oil production increased significantly compared with that of 1976; the increase came from the Bombay High offshore oilfields, which began producing in May 1976. This offshore production contributed nearly 15% of total production, and several new wells were brought online during the year. Additional production platforms were being installed and a large increase in output was expected in 1978. Onshore production was nearly stable because output from some of the older fields was declining and a few new wells came online to maintain production.

Despite the encouraging rise in domestic production, India was still required to increase its imports by over 1 million tons in 1977 because demand rose faster than an ambitious exploration program could discover new supplies. Iran supplied about 40% of crude oil imports, and Iraq, Saudi Arabia, the U.S.S.R., and the United Arab Emirates accounted for most of the remainder. The total cost of both crude oil and finished-product imports reached a new high of $1.85 billion, a sizable increase over the 1976 total and about 30% of India's total import bill.

Two new refineries were under construction during the year—the 1-million-ton-per-year Bongaigoan refinery in Assam and the 6-million-ton-per-year Mathura plant in Uttar Pradesh. The Government ordered that particular attention be given to the design of polution-control equipment for the Mathura refinery because of its proximity to historical sites.

Construction continued on the major Salaya-Koyali-Mathura pipeline, which will bring crude oil from the Bay of Cambay to the Koyali and Mathura refineries. The U.S. firm Brown and Root Inc., working under contract to ONGC, began laying a 76-centimeter-diameter crude oil pipeline and a 66-centimeter-diameter natural gas pipeline from the Bombay High offshore oilfield to Uran on the coast near Bombay port, a distance of 200 kilometers. Completion of the lines in mid-1978 was to allow an increase in crude output and utilization of the natural gas, which is now reinjected into the oil reservoir or flared.

India was trying to expand its oil and gas resources as quickly as possible and was conducting an active exploration program both onshore and offshore. ONGC drilled 37 wells onshore and 13 wells offshore, and Oil India Ltd. drilled 10 wells. At yearend, three foreign rigs were working offshore on contract to ONGC. In addition, ONGC operated its own jackup rig, Sagar Samrat. Drilling on other geologic structures in the Bombay High area has proven additional oil discoveries of undetermined extent. Gas reserves, however, appeared to be much larger than originally believed. The Indian west coast industrial plans may need reassessment in light of the apparent favorable reserve situation, especially in regard to the fertilizer and electric power sector.

The Mineral Industry of Indonesia

By K. P. Wang[1]

Real growth in the Indonesian economy was about 7% during the fiscal year from April 1, 1977, to March 31, 1978, with exports providing the main impetus to expansion.[2] International monetary reserves were improved by $650 million, with reserves now surpassing $2 billion.[3] Prudent monetary and fiscal policies reduced inflation to a 10% annual rate and restored the confidence of the international financial community. President Suharto was reelected, portending stability and continuity of existing policies for the next 5 years. Oil revenues leveled off, and the long-term future of petroleum showed some uncertain aspects. Agricultural performance did not reach expectations with regard to closing the food gap and increasing traditional exports such as tobacco, tea, coffee, pepper, and palm oil. Recognition of the need for improving the investment climate gave hope at yearend that more foreign capital may be forthcoming.

Indonesia's gross national product was about $37 billion in 1976 and possibly exceeded $44 billion in 1977, measured in current prices. Oil output value increased from about $8 billion in 1976 to $9 billion in 1977. Gross petroleum exports in 1977 amounted to about $7.2 billion, contributing nearly 70% of total gross exports and one-half of Government revenues. Exports of liquefied natural gas (LNG) entered the trade accounts for the first time, although registering only $78 million in fiscal year 1977-78 compared with $400 million expected by 1980. Low world prices continued to plague both the nickel and copper industries. Royal Dutch/Shell Group's decision to delay development of its coal concession in Sumatra was a setback to the nonoil mineral economy, although the Government made progress in developing its own coal properties. High tin prices yielded record revenues for tin producers. Expansion programs in the cement and fertilizer industries made significant headway.

During 1977, the "hard rock" part of the mineral industry, which excludes oil and gas, fertilizers, cement, and iron and steel, consisted primarily of the operations belonging to three State mining companies and half a dozen relatively important private mining companies. P.N. Tambang Batubara, the State coal company, was trying to build up two small coal mines in Sumatra called Bukit Asam and Ombilin. Shell Internationale Chemie Mijnbouw B.V. has a production-sharing contract with Batubara to eventually develop a 10-billion-ton coal reserve property in Sumatra.

P.T. Tambang Timah is the large Government tin firm that controls most of the tin reserves as well as Indonesia's only tin smelter. Its new *Banka II* dredge designed to excavate 6.9 million cubic yards annually was being readied for service, and purchase of two additional large dredges for the Belitung and Kundur mines was being considered. Dutch-owned Billiton Exploratie Maatschappij Indonesia B.V., a subsidiary of Royal Dutch/Shell, was awaiting the arrival of an 8-million-cubic-yard-per-year dredge for use on its offshore leases. P.T. Koba Tin of Australia ordered two small tin dredges to supplement gravel pumps.

P.T. Aneka Tambang, the third State mining company, has responsibility with regard to all "hard rock" minerals except coal, tin, and radioactive minerals. In 1977, it produced 968,000 tons of 2.2% to 2.4% nickel ore at its Pomalaa mine in South-East Sulawesi for export to Japan, along with ferronickel at a plant built locally to utilize the low-grade nickel ores from the mine. Aneka Tambang's Bintan Island

Digitized by Google

bauxite mines produced 1.3 million tons of bauxite during 1977, up 38% from the tonnage in 1976, all for export to Japan. Aneka Tambang was considering building a large alumina plant on Bintan and a steel billet plant to utilize the iron sands it produces.

P.T. International Nickel Indonesia (P.T. INCO) started construction of the second phase of its $850 million nickel project at Soroako, Central Sulawesi, which would eventually bring nickel-in-matte capacity to about 50,000 tons annually; a third phase was being planned, although there was great hesitancy on the part of the Canadian management to complete the project because of depressed nickel prices. The Ertsberg property of U.S.-owned Freeport Indonesia Inc. continued to suffer from low copper prices, and its management was hesitant to expand operations underground. A joint venture with Japan in chromite started production, and a joint venture with the United Kingdom in granite was trying to sell a surplus to Singapore. Work finally got underway on the mammoth Asahan hydroelectric powerplant and aluminum smelter project in North Sumatra. However, P.T. Indonesia Asahan Aluminum, a joint venture between the Indonesian Government and a Japanese consortium organized to develop the project, had to refinance it because of skyrocketing costs to over $2 billion, 2.5 times the original estimate of $800 million.

In June, P.T. Rio Tinto Indonesia signed a contract of work with the Indonesian Government covering an area of approximately 17,200 square kilometers in North Sulawesi. This was the first contract signed by the Indonesian Government with a foreign-owned mining company within the context of its "Third Generation Mining Contracts for Work." Thus, Rio Tinto Indonesia obtained rights to exploration and production of minerals other than oil, natural gas, and radioactive minerals. Exploration and other preproduction rights are vested in Rio Tinto Indonesia for up to 8 years and production rights, up to 30 years thereafter. The agreement also provides that an interest of up to 51% be offered to the Indonesian Government or its nominees over a 10-year period from the start of any mining operations. This contract is not only significant for Indonesia but could prove an important precedent for developing-country agreements elsewhere.[4]

The oil and gas industries made notable gains in production, with the large producer P.T. Caltex Pacific Indonesia maintaining the general level of the last few years and various lesser firms expanding output. The most notable gain was made by the French firm Total Indonesie at its Handil Field, but Union Oil Co. of Indonesia (a subsidiary of Union Oil Co. of California), with its main field Attaka; Atlantic Richfield Indonesia, Inc. (Arco), with its Arjuna Fields; Independent Indonesian American Petroleum Co. (IIAPCO), with its large field at Cinta; and Petromer Trend Corp., which operates in Irian Jaya (formerly New Guinea), also did well. The two large LNG projects, which may eventually cost nearly $2 billion, came into their own with regard to first-phase facilities. Specifically, Roy M. Huffington, Inc.'s (Huffco) Badak gasfield (some oil also) and the LNG plant in East Kalimantan were brought into production, and Mobil Oil Indonesia Inc.'s Arun gasfield (oil as well) and its corresponding LNG plant near Lho'seumawe were near completion. The Japanese side of the deals remained firm, whereas the U.S. west coast market became uncertain. Mobil has plans to build second-phase facilities as large as the first, in order to sell to the United States.

The latter part of 1977 and the first part of 1978 were a significant period in Indonesia's oil history. The final U.S. Internal Revenue Service (IRS) ruling clearly removed the double taxation threat from U.S. oil companies operating in Indonesia. (See Petroleum.) The State oil firm Perusahaan Negara Pertambangan Minjak dan Gas Bumi Nasional (Pertamina) offered new financial incentives and generally retreated to the standard production-sharing contract with regard to foreigners. As a result, exploration investments and the number of seismic crews and drilling rigs have risen about 50%. The immediate increase in exploration, however, may portend an initial decline in oil and gas production. At least four new joint venture contracts were being arranged, the latest with the Federal Republic of Germany's Deminex and Japan's Teikoku Oil Co., Ltd. The contracts would call for the foreign companies and Pertamina to share cost and production on a 50-50 basis, divide equally the oil and gas produced from specific areas, and conclude a standard production-sharing arrangement (an 85-15 split after recovery of costs) for the 50% of output retained by the foreign partner. The foreign firms would be obliged to offer 5% of their share to Indonesian investors once oil is discovered and to sell part of their output domestically. Deminex will work on a coastal strip in East Kalimantan, and Teikoku reportedly acquired rights in Djambi Province in southern Sumatra.

Digitized by Google

With the reorganization of the Ministry of Mines into the Ministry of Mines and Energy, Indonesia's new energy policy began to take shape.[5] The pessimists say that Indonesian oil is exportable for only 15 years, and optimists predict no more than twice as long; however, there is clear agreement that energy conservation and efficient utilization concepts must be introduced and other forms of energy must be used as much as possible. Maintaining large exports of oil is fundamental, in any case, to earning the necessary foreign exchange. The substantial amounts of natural gas now being flared or capped could be put to work as domestic fuel. Development of the coals of Sumatra and, to a lesser extent, of Kalimantan (or Borneo) is considered important in energy policy. Hydropower potential may be close to 30 million kilowatts, and the hope is to increase production from less than 500,000 kilowatts to about 4 million kilowatts by the year 2000. The Indonesians say that the geothermal power potential may be as much as 8 million kilowatts, so development of nearly 500,000 kilowatts seems reasonable. Uranium should become important, with commercial deposits already found in Kalimantan and Sumatra. Firewood could be better utilized in rural areas. Solar energy may come into its own. A system of identifying specific energy resources and defining development priorities is a major aspect of the new policy.

PRODUCTION

Indonesia's mineral production showed sharp increases in bauxite, mine nickel, nickel products, mine tin, asphalt, cement, fertilizers, natural gas, crude oil, and refinery products; moderate increases in refined tin and iron sands; and reductions in mine copper, precious metals, and manganese. The program to rapidly increase cement capacity was gaining momentum, and other construction materials did reasonably well also. Despite a very impressive gain in natural gas output, more than half was still flared or capped. LNG projects came into their own. Development of the petrochemical and fertilizer industries also made significant headway. Production of nickel matte reached only two-thirds of phase 1 capacity and output of ferronickel was still under capacity, but production of mine nickel increased substantially during 1977, with new ore extracted for the smelter along with traditional ore for export. Mine copper output declined in both tonnage and value, with prices still very low. Indonesia's tin, nickel, oil, gas, and fertilizers are of considerable world consequence.

[e]Estimate. [p]Preliminary. [r]Revised. NA Not available.

[1]Includes gold and silver content of copper ore and output by Government-controlled operations. Gold output by operators of so-called "People's" mines is unavailable but may be as much as 30,000 troy ounces per year.

[2]Excludes mine output directly converted into ferronickel and includes a small amount of cobalt which is not recovered separately.

[3]Data represent quantities of limestone used for cement production and exclude considerable amounts of limestone produced by enterprises under local jurisdictions for building materials, for crushed rock to be used as aggregate, and to burn for lime.

[4]Sulfur produced by other than the Frasch process.

TRADE

Indonesia's favorable balance-of-payments position improved further, with a surplus of $1.19 billion in 1977 compared with $0.74 billion in 1976. Oil exports increased considerably, and Pertamina's financial problems were being resolved. During 1977, total exports increased to $10.5 billion and total imports increased to $7.3 billion.

As would be expected, the largest share of Indonesia's trade is with Asia. In 1977, approximately 56% of all exports went to Asian countries, and roughly 58% of all imports came from Asian countries. Imports from Japan were about 28% of total imports, and exports to Japan represented approximately 40% of total exports. The United States continued to be Indonesia's second most important trading partner, furnishing about 13% of Indonesia's imports and taking about 28% of Indonesia's exports. Europe's share in 1977 was about 18% of the imports and just under 10% of the exports.

Digitized by Google

Equipment and machinery represented roughly 40% of all imports in 1977. However, base metals aggregated 12%, mineral products 13%, and chemical products 8%.

Minerals, particularly oil, continued to be of overriding importance in total exports. Oil represented 68% of 1977 exports in value, and other minerals added another 3.5%. Gross receipts from Indonesia's exports were as follows, in million dollars:

Commodity	1975	1976	1977
Petroleum	5,311	r5,080	7,190
Tin	154	165	236
Copper concentrates	74	80	e80

COMMODITY REVIEW

METALS

Aluminum and Bauxite.—Aneka Tambang's high-silica trihydrate bauxite mines on Bintan Island near Singapore produced at a rate considerably higher than in 1976, as reflected by Japan's reported imports from Indonesia of 967,255 tons in 1976 and 1,207,699 tons in 1977. So far, Japan has been the sole purchaser of Indonesian bauxite. Aneka Tambang moved ahead on a $450 million (previously $400 million) alumina project on Bintan to produce 600,000 tons of alumina annually. An earlier Soviet offer to help with a large loan never reached fruition. However, a feasibility study made by Kaiser Engineers International Inc. probably will still be used by the new consortium about to be named to carry out construction of the alumina project. The Klöckner interests of the Federal Republic of Germany, together with Aluminum Co. of America (Alcoa) as a lesser partner, have the best chance of landing the contract, and Saudi Arabia may extend a loan. The plan is to sell most of the alumina produced in the future to the Asahan aluminum complex to be built in Sumatra and to provide 150,000 tons for export, possibly to the Middle East, by the early 1980's. The Bintan project will probably take at least 42 months to complete.

The initial plan for the Asahan aluminum and hydropower project is to develop just over 500,000 kilowatts of electricity on the Asahan River in North Sumatra, about one-half each at Sigura-gura and Tangga. About 80% of the electricity will be used by the aluminum plant, leaving the rest for general distribution. The powerplant site is near Toba Lake, a sightseeing resort 260 kilometers from the port of Balawan. The aluminum plant of 225,000-ton-per-year capacity presumably will be built at Kuala Tanjung, 120 kilometers from the powerplant and 45 kilometers east of Tebingtinggi. A good-size port is included in the plans. Indonesia considers the Bintan alumina complex and the Asahan aluminum complex and powerplant as important foundations for its emerging power, chemical, and heavy industries.

The Asahan aluminum project, a symbol of Indonesian-Japanese economic cooperation, ran into serious financial difficulties at yearend.[6] Asahan was scheduled to be one of the most important projects in Indonesia's second 5-year plan and its largest single foreign investment venture. The Japanese view it as not only a great technical challenge but a source of low-cost aluminum. Virtually all of the large Japanese

Digitized by Google

aluminum companies, along with the Japanese Overseas Cooperation Fund, have banded together into a consortium to work on this very significant project, and the Indonesian Government committed itself to a 10% equity stake initially; the resultant joint venture is known as P.T. Indonesia Asahan Aluminum.

Construction costs, including infrastructure and research expenses, were originally estimated in 1975 at just over $800 million, including about 30% for electric power development, 60% for aluminum-smelting facilities, and 10% for long-term working funds. However, by yearend 1977, the expected overrun was in excess of $1 billion, owing to the sharp increase in the value of the yen, inflation, proposed hydroelectric powerplant design changes, and similar commitments by Japanese aluminum companies in another aluminum project in Brazil. The original plan was to complete the project by about 1984, but many thorny financial problems must be solved before construction can be undertaken.

Chromite.—Chromite output was officially reported for the first time in Indonesia. Apparently, about 5,000 tons of 40%- to 42%-Cr_2O_3-grade chromite was produced in the country during 1977, with a value of $65 per ton f.o.b. The Indonesian firm P.T. Perto and Japan Sulawesi Chrome Development, Ltd., had earlier provided an initial outlay of $1 million to investigate an area 35 miles south of the port of Parepare in Sulawesi with the hope of eventually producing 20,000 to 40,000 tons of chrome (or chromite) annually.

Copper.—Freeport Indonesia's predominantly private Ertsberg operation in Irian Jaya (Indonesia's only primary copper producer) had a reasonably successful year in a technical sense but a difficult year financially, in view of the low copper prices. The average copper price went down from $0.64 per pound in the first half of 1977 to $0.55 per pound in the second half of the year, below Freeport Indonesia's break-even point of close to $0.59 per pound. Yet for general reasons, a shutdown was not feasible. There were also some local political disturbances that affected output and shipments somewhat. Actual production in 1977 dropped below the 190,000-ton level in terms of concentrates, a sizable decline from the 1976 level. Approximately two-thirds of the output went to Japan and the rest to the Federal Republic of Germany for smelting, although these countries were reluctant to take these amounts because of the worldwide recession. The company is expected to be under considerable strain to repay debt obligations, which amount to $17 million to $18 million annually in 1978-80.[7]

Ertsberg means "ore mountain," and mining of this ore body in the hills is presently by open pit methods, with ore brought down to the mill at a lower level and concentrates finally slurried to the sea-level port of Amampare. The concentrate pipeline was damaged in July but was subsequently repaired. Exploration was continuing on an underground mine realized zone about 1 mile east of the open pit, with a 1,400-meter tunnel being driven for collecting samples. Fluor Corp. is in charge of this project, which is scheduled for completion by yearend 1978, at which time a decision will be made as to whether or not to open up an underground mine also.

A copper exploration project controlled by Taiwan Metal Mining Co., with 45% Singapore money and 10% Indonesian money, made some headway during 1977. This joint undertaking, called P.T. Copperindo, was working under a "Third Generation Mining Contract" to search for copper in the Tasikmalaya area of West Java. Initial drilling proved promising, and inquiries were being made to engage the services of Morrison-Knudsen International Co. of San Francisco to do a feasibility study.

Gold and Silver.—Indonesia was exploring in the Cimari and Lembak Seembada areas of West Java during 1977 as part of its efforts to support and perhaps expand the Cikotok gold and silver mine in southern Banten, the only sizable gold operation in Indonesia. This mine is owned and operated by the State corporation Aneka Tambang. A preliminary survey showed that reserves here would only last about 10 years at recent production levels. In fact, its output has been declining, of gold from 10,700 troy ounces in 1976 to 8,230 troy ounces in 1977 and of silver from about 153,000 troy ounces in 1975 to 109,000 troy ounces in 1976 and 91,000 troy ounces in 1977.

Precious metals are also produced as byproducts of copper from the Ertsberg mine whose concentrates analyze about 0.297 troy ounce of gold and 3.70 troy ounces of silver per ton. Thus, gold output from copper was approximately 56,000 troy ounces in 1977 and silver output, nearly 700,000 troy ounces. Because of the difficulty in selling copper, precious metals byproduct production declined about 13% from that of 1976.

Aneka Tambang also discovered gold reserves in southern Kalimantan. Indonesia actually produces much more gold than has been recorded as stated here. It has been said that unrecorded production of precious

Digitized by Google

metals from small mines in Kalimantan and Sumatra may be several times the quantities mentioned for the Cikotok enterprise.

Iron and Steel.—Indonesia's 1977 steel news was still centered around Government-owned P.T. Krakatau Steel, with facilities at Cilegon in West Java, 75 miles west of Jakarta. The historical background of this enterprise was described in the 1976 edition of this chapter. Two small steel mills—a 150,000-ton-per-year reinforcing rod mill and a 100,000-ton-per-year angle mill—were completed in early 1977, and others are to be built. Krakatau's 4-unit HyL-process direct-reduction plant was moving ahead roughly on schedule. Each unit is rated at about 500,000 tons per year of sponge iron and is designed to use Australian high-grade iron ore and natural gas from the Arjuna offshore field in Central Java.[8] All units were under construction at yearend, with the first unit planned to be operational in 1979 and the others a year or more later. About 500,000 tons of the sponge iron will be consumed by Krakatau itself to make steel, the same amount will be sold to private Indonesian steelmakers, and the remaining 1 million tons will be exported in the first years of operation.

Indonesia's annual steel demand already exceeds 1.5 million tons, with prospects of doubling by 1985 and reaching 4 million tons by 1990. Development of the integrated Krakatau steelworks is aimed at meeting part of the future demand. The country actually has just over 30 small private steel plants.[9] Together, these plants can manufacture more than 1 million tons per year of steel products, mostly bars, rods, ingots, billets, and pipes. At least seven of these plants produce billets from scrap, whereas most of the others work on imported semimanufactures. In 1977, local producers were having trouble from foreign competition.

The Indonesians hope to develop some local iron ore in the future, from places such as the Lampung area of South Sumatra and areas in Kalimantan. Meanwhile, the plan is to use imported iron ore. However, the country produces small quantities of iron sands for sale to Japan, which reported imports of 283,310 tons in 1976 and 279,725 tons in 1977. The sands analyze about 55% iron and 10% titania and are produced by Aneka Tambang east of Tjilatjap along the southern coast of Java. Of late, the Indonesians have been thinking about exchanging oil for Brazilian high-grade iron ore, for use by the Krakatau enterprise.

Manganese.—Indonesia's output of manganese ore declined further to about 6,000 tons (88% MnO_2 grade) in 1977, less than one-third of the peak output of 1974 and less than one-half of the output of 1975. Lack of demand from Japanese buyers brought about the steady drop in manganese production, with some producers accumulating moderate stockpiles. All the mines are small, and most work is done manually, as the majority of the mines are in Java where foreign operations are not permitted in manganese extraction except under special circumstances. Apparently, P.T. Gama Karya has a deposit near Pulau Doi, P.T. Miga Lima has a deposit in Bima (located within West Musatenggara), and P.D. Perusahaan Pertamgangan Yogyakarta was trying to develop a 10,000-ton-per-year mine with the help of the Japanese.[10]

Nickel.—Aneka Tambang, Indonesia's State mining company for nonfuel minerals other than tin, has indicated that known nickel reserves in the country may be about 14 million tons of nickel content or possibly 15% of the world's reserves.[11] Gag Island nickel reserves may be 6 million tons, and Central Sulawesi's reserves may be on the order of 3 million tons. Indonesia's resources are all nickeliferous laterites, containing more than 25% water and 1% to 3% nickel in the ore; these laterites are much more expensive to process than the sulfides which are extracted, for example, in Canada.

Indonesia's nickel in all forms will be entirely exported until the country develops a viable steel industry. However, there will always be large surpluses. In 1977, Japan imported the entire output of high-grade (about 2.2% to 2.4% nickel) nickel ore from Aneka Tambang's mine at Pomalaa in South-East Sulawesi. Aneka Tambang's new ferronickel smelter (4,000 tons per year of contained nickel) is designed to use the lower grade ores of Pomalaa. Japan took 6,321 tons of this ferronickel in 1976 and 8,605 tons in 1977. The 75% nickel matte produced by P.T. INCO at Soroako was mostly exported to Japan.

Indonesia's largest nickel project, the Soroako enterprise in Central Sulawesi owned 75% by the Canadian firm Inco Ltd. and 25% by Japanese firms, was having startup and slowdown problems in 1977. P.T. INCO was working seven local deposits to supply 2.2% nickel ore to its new matte smelter whose phase 1 processing line, rated at 16,800 tons per year of contained nickel, was completed in late 1976. To make 75%-grade nickel matte, P.T. INCO obtains sul-

Digitized by Google

fur from its parent company in Canada. At yearend, phase 1 of the smelter was still running at only two-thirds of capacity because of ore-grade control problems (it was employing selective mining) and malfunctioning of the 100-meter-long reduction kiln in handling sticky (high-moisture) uneven-grade ores. Upgrading the crude nickel matte from rotary kiln and electric furnace into high-grade nickel matte in converter presented no problem.

Two other similar-size processing lines for phase 2, scheduled to be completed by 1978, were delayed at least until 1979 because of the need to redesign kilns and the generally depressed world nickel market. Phase 2 operation is also contingent upon completion of a 165,000-kilowatt powerplant on the La Rona River. Although the latest figure mentioned for capital cost was $850 million, it would hardly be surprising if the actual cost were higher. At the height of construction, there were 11,000 workers, compared with 4,000 expected when the project is totally completed. Most output will go to the Japanese market in the next few years, with prospects of ultimately selling to the People's Republic of China also.

Construction of P.T. Pacific Nikkel Indonesia's project on Gag Island, off the western extremity of Irian Jaya, has been delayed until at least 1979, with the completion date moved back to 1983. In view of the large capacity of this proposed project—51,000 tons per year of nickel powder or briquets and 1,000 tons per year of nickel and 550 tons per year of cobalt contained in mixed sulfide concentrates—development of the Gag Island project, along with the Soroaka project, would propel Indonesia into a prominent world position in nickel production. Pacific Nikkel has already spent $50 million on this project, which may cost as much as $1 billion to implement. United States Steel Corp., the Dutch steelmaker Hoogovens IJmuiden B.V., Newmont Mining Corp., Sherritt Gordon Mines Ltd., and Mueller Co. were the initial partners of the consortium. However, the latter three backed out, although Sherritt Gordon is still interested in participating in the role of technical consultant. Meanwhile, Amoco Minerals (a subsidiary of Standard Oil Co. of Indiana) joined up as partner, and the Indonesian Government agreed to take 20% equity for World Bank financing purposes. The original consortium had a 30-year work contract dating from 1969, and negotiations were made to extend the project's preconstruction exploration permit another 18 to 24 months because of the depressed world market for nickel. Using a cutoff grade of 1.5% nickel ore, reserves may be twice as much as P.T. INCO's project in Sulawesi.

Tin.—Indonesia's tin output continued to rank behind that of Malaysia, the U.S.S.R., and Bolivia and just ahead of Thailand and the People's Republic of China. Actual reported production of both mine and refined tin were in the 24,000- to 26,000-ton range in 1977, which was roughly one-half of the historic output level in the case of mine tin. The output value increased by about $75 million, judging from tin exports of $236 million. Prices rose sharply during 1977, reaching considerably over $5 per pound near yearend. These high prices stimulated smuggling activities, and the result was that at least 1,000 tons of mine tin was smuggled out of the country without being reported as production. Expansion plans underway indicate that mine output in the year ahead might be 3,000 tons greater than in 1977. Almost all of the local concentrates were smelted at Indonesia's only tin smelter located at Muntok on Bangka Island. Consideration is being given to installing a fourth reverberatory furnace at this smelter to replace the West German rotaries now being operated, and increasing capacity slightly in the process.

Timah, the State-owned tin company, dominates the tin industry, controlling well over 90% of the concentrates produced and all of the refined tin. Timah's tin comes primarily from three famous tin islands south of Singapore and east of Sumatra. Timah's mine tin production in 1977 was 17,721 tons on Bangka, 4,800 tons on Belitung, 1,411 tons on Singkep, and 88 tons at Bangkinang. In total, the company has about 500,000 tons of recoverable tin reserves. Timah's "crash" exploration program yielded important additional reserves on Belitung, reestablishing the island's operating life at about 30 years. As of yearend, Timah had twelve 9- to 18-cubic-foot-bucket fixed dredges on Bangka, fourteen 5- to 14-cubic-foot-bucket fixed dredges on Belitung, and four 5- to 14-cubic-foot-bucket fixed dredges on Singkep. Timah's 22- to 24-cubic-foot-bucket dredge capable of digging to a depth of 50 meters, ordered from the United Kingdom's F. W. Payne but being built by Japan's Mitsubishi Heavy Industries, Ltd., for $21 million, might be ready for service before the end of 1978. This dredge, to be named *Bangka II*, is designed to excavate 6.9 million cubic yards annually.

Billiton has offshore contract rights in an area between Bangka and Singkep Islands.

Digitized by Google

This firm, with shares and board members from Timah, has ordered the world's largest-bucket tin dredge for work near the Tujuh Islands. This "monsoon weather," $25 million dredge being built at the Jurong shipyard in Singapore will have 30-cubic-foot buckets capable of dredging about 8 million cubic yards per year at a 45-meter depth.[12] It should be ready for service before yearend 1978. In addition to the Tujuh Islands, where reserves have been initially estimated at 15,000 tons of recoverable tin good for about 6 years of operations, Billiton has a 40-year concession elsewhere, dating from 1968.

P.T. Hill Pty. Indonesia, a subsidiary of Broken Hill Pty. Co. Ltd. (BHP) of Australia, was having a very difficult time trying to develop some business in Indonesia. However, the board chairman of Australia's largest publicly held industrial concern indicated that BHP has no immediate plans to pull out and intends to work out future plans with the Indonesian Government. BHP's concessions extend only to nonalluvial tin deposits, and its main interest has been the Kelapa Kampit underground mine on Belitung. BHP's investment of more than $10 million already to rehabilitate this flooded old Dutch mine has created only a marginally profitable enterprise despite very high prices. Reserves cannot be ascertained unless large expenditures are made to dewater the lower portions of the mine. There is a pilot-scale concentrate. The mine produced 296 tons of mine tin in 1977.

Koba Tin, a subsidiary of Kajuara Mining Corp. Pty. Ltd. of Australia, with one-fourth of the shares belonging to Timah, produced 1,610 tons of mine tin in 1977 from its Nibung property on Bangka. Another property called Lubuk-Besar was shut down temporarily. Koba Tin has onshore reserves on 350 hectares amounting to 35,000 to 47,000 tons of mine tin and unreported quantities of reserves offshore on 2,800 hectares.[13] Koba Tin started with gravel-pump operations but has since ordered two small 3-cubic-foot-bucket dredges. All of the tin produced by this company is marketed and smelted through Timah.

NONMETALS

Cement.—Indonesia was on schedule in its plans to raise cement output by about 5 million tons during the 5-year period ending in 1980 and by more than 5 million tons again by 1985 when national demand is expected to exceed 12 million tons. The objective is to attain self-sufficiency as the country moves rapidly forward in its industrialization program.

Cement production in 1977 increased by nearly 900,000 tons over the 1.8 million tons produced a year earlier, and prospects are that 3.5 million tons will be produced in Indonesia during 1978.

P.T. Semen Cibinong, an Indonesian private joint venture with Kaiser Cement & Gypsum Corp., completed its first-stage expansion program in 1977 at a cost of about $50 million, with Fuller Co. supplying the key equipment. Annual capacity of its West Java plant was raised to 1.2 million tons in the process. Cibinong hopes to double capacity again during the third 5-year plan period ending in 1984. With net earnings of over $10 million, Cibinong enjoys a tax holiday through September 1980.[14]

P.T. Semen Gresik, a Government firm engaging the engineering services of Morrison-Knudsen, was in the process of tripling the capacity of its plant in East Java to 1.5 million tons per year by 1978. P.T. Semen Padang retained F. L. Smidth & Co. to build a 700,000-ton-per-year dry-process plant next to its old wet-process plant located in Indarung, West Sumatra. Another cement works, Indarung 3, is scheduled for completion before 1985. Mitsui & Co., Ltd.'s 600,000-ton-per-year plant at Cilacap in Central Java was nearing completion, with a second plant on the drawing board. Other cement works scheduled to be built include Tonasa 3 in South Sulawesi, Mohorok 1 in North Sumatra, and plants in East Nusa Tenggara, Irian Jaya, and Cirebon. Kawasaki Heavy Industries Ltd. will build a clinker plant at Bataraja and grinding plants at Palembang, both in South Sumatra.

Fertilizer Materials.—Indonesia's program to achieve self-sufficiency in fertilizers, based primarily on effective utilization of domestic natural gas resources, made significant headway in 1977. At the start of the year, Indonesia had only about 530,000 tons per year of urea capacity (urea contains 46% nitrogen), although three 570,000-ton-per-year urea plants were being built, and two more plants of the same size were planned. One of the large projects undergoing expansion is the Pusri ammonia-urea complex near Palembang in South Sumatra, with Kellogg Overseas Corp. having the management responsibility. The Pusri III and Pusri IV units, which are of the standard 570,000-ton-per-year size, had been completed by yearend, bring-

Digitized by Google

ing the total annual capacity of the complex to about 1.6 million tons. Kellogg has also been constructing another 570,000-ton-per-year urea plant at Cikampek in West Java for P.T. Kujang, scheduled for completion at yearend 1978 with the help of a $200 million Iranian loan. Still another urea plant of this size, being built by August Thyssen-Hütte AG at Aceh in North Sumatra for the Association of Southeast Asian Nations (ASEAN), was also well on the way toward completion. The country's ammonium sulfate capacity was being expanded to approximately 300,000 tons per year. Indonesia was also building triple superphosphate and compound fertilizer plants at Gresik and elsewhere.

Iodine.—Iodine has been produced in East Java for several decades. The only important current producer is P.T. Kimia Farma, whose plant at Mojokerto provided 33.0 tons of iodine in 1975, 27.3 tons in 1976, and only 20.5 tons in 1977. Indonesian iodine is used in the pharmaceutical industry. The Japanese firms Mitsui and Ise Chemical Industries Co., Ltd., were hoping to develop additional iodine prospects in Indonesia in cooperation with Kimia Farma; however, no production had as yet been reported.

Stone.—*Granite.*—P.T. Karimun Granite, a joint venture with British Bovis Engineering of Hong Kong, was Indonesia's sole producer of granite in 1977. The bulk of the production was used in constructing Pertamina's LNG facilities in North Sumatra and East Kalimantan. Pertamina's financial difficulties, however, have forced Karimun Granite to sell its surplus to Singapore. Output in 1977 was about 670,000 tons, only one-fourth of the long-term annual target planned for the 1980's.

MINERAL FUELS

Coal.—Indonesia has only a minor coal industry. In 1977, two small coal mines together produced only 231,000 tons of medium calorific value subbituminous coal. Both mines are located in Sumatra. The Bukit Asam mine near Palembang, with possibly 150 million tons of hard coal reserves and nearly 2 billion tons of lignite, might be expanded to 2.5 million tons per year by 1985. The Ombilin mine near Padang, with 100 million tons of reserves as an order of magnitude, has a chance to be expanded to roughly 1 million tons per year. The Japanese firm Sumitomo Coal Mining Co., Ltd., was interested in this mine as a source of steam coal imports and will undertake a feasibility study before making any commitments. The Indonesians have become increasingly interested in developing coal for domestic and foreign markets to cut down on oil use and free more oil for exports. The Government coal company Batubara was created both to produce coal and to direct the coal development program, and is thus in charge of the Bukit Asam open pit operations and the Ombilin underground operations.

Batubara was getting ready to start implementing a very substantial project based on the Bukit Asam mine in South Sumatra. Upgrading and expanding this mine would entail possibly $100 million. However, the project calls for investing $35 million to improve railroads for shipping the coal out, $85 million for ports and a sea transport system to move coal to West Java, $450 million for two 375-megawatt generators and related facilities, and $350 million for transmission lines and a power supply grid in Java. The World Bank will assist in the project, and additional short-term borrowings will be sought also. Dravo Corp., Fluor Corp., and Morrison-Knudsen of the United States, Mineral Engineering of Canada, and Davy International Ltd. of the United Kingdom are among the firms interested in bidding for the contracts.[15] This project will be mainly for the domestic market, supplying fuel for power and raw materials for industry.

A much larger deposit near Bukit Asam was discovered by Shell International, of the Royal Dutch/Shell Group. Reserves are said to be 10 billion tons, but the coal is high in water content and is basically lignitic. A production-sharing contract signed with Batubara, committing Shell International to possibly $1 billion and up to 25 million tons of annual output, however, was postponed indefinitely in late 1977. The coal quality was not up to expectations, and the hoped-for Japanese market was not receptive for the time being.

Natural Gas.—Indonesia's natural gas is expected to become a major foreign exchange earner by the 1980's, although it is overshadowed by crude oil. Most of the natural gas is flared or capped. However, a pipeline was completed between Cilegon and the Jakarta area near yearend that is intended to supply natural gas to cement, steel, and fertilizer plants in the near future. Gross output of natural gas in Indonesia was reported at 533 trillion cubic feet in

Digitized by Google

1977, compared with 222 trillion cubic feet in 1975. A basic factor affecting the expansion of natural gas production is the success of the two large LNG projects—the Badak Field in East Kalimantan developed by Huffco and the Arun Field in North Sumatra developed by Mobil.[16] How much LNG can be sold to the United States and Japan clearly affects plant completion and production schedules. Both LNG plants are joint ventures with Pertamina.

The Badak gasfield is also a small producer of crude oil and has the potential to produce 50,000 barrels per day. The plan is to eventually produce 550 million cubic feet of natural gas per day for the local LNG plant, the first section of which was completed in late 1977. Two additional gas-processing trains were being considered for Badak. The Arun Field, near Lho'seumawe, will initially have three trains, to be completed by fall of 1978, with additional expansion contemplated. The Arun LNG plant will be rated at 1 billion cubic feet of natural gas per day; the oil and gas field supplying it might eventually also produce 100,000 barrels per day of crude oil. The Arun project calls for construction of a 16-inch gas pipeline and a 42-inch condensate pipeline over a distance of 20 kilometers. Full production from the two projects, which together may cost $2 billion, is not expected until the mid-1980's. The total foreign exchange balance of these two projects for the remainder of the 20th century may run up to $8 billion. There was some controversy regarding the U.S. west coast market in the immediate future.

Petroleum.—Indonesia's 1977 oil production, which ranked 14th in the world and constituted 2% of the world total, was up 11.8% from the approximately 1.5 million barrels per day in 1976. The bulk of this was exported as crude oil, as Indonesia's refinery capacity is not particularly large. In 1977, Indonesia produced 615 million barrels of crude oil, exported 484 million barrels, and refined 154 million barrels. About 51 million barrels of the refinery products ultimately derived was exported also. Overall oil exports netted $6.5 billion in 1977, compared with less than $6 billion in 1976. In 1977, 48% of Indonesia's crude oil exports went to Japan and 37% went to the United States.

In 1977, Caltex's share of national output was about 50%, compared with 63% in 1975. Caltex's output did not show much change, whereas lesser companies made significant advances. Caltex produces low-sulfur Minas light crude, famed the world over. Caltex, with facilities mainly near the coast in central Sumatra, produced 304 million barrels in 1977. Ranked next was Total Indonesie with 84 million barrels (nearly triple its 1976 output), followed by Union Oil with 50 million barrels, Arco with 48 million barrels, IIAPCO with 41 million barrels, Pertamina with 32 million barrels, Petromer Trend with 28 million barrels, and P.T. Stanvac Indonesia with 12 million barrels. During 1977, U.S.-affiliated companies produced about 85% of Indonesia's oil.

Pertamina's importance goes far beyond its output of roughly 5% of the country's crude oil in 1977. It owns all of Indonesia's refineries, controls the international and domestic petroleum distribution system, operates a fleet of tankers and other ships, plays a strong role in pipelines and terminals, and is involved in dozens of joint ventures and enterprises, including many nonindustrial projects. Pertamina represents the Government in foreign oil contracts and supervises international oil contractors and service companies. Pertamina's debts resulting from overspending were gradually brought under control by quick action on the part of the Government, which assumed control of its business dealings, installed new management, and reevaluated all projects.

Favorably impressed with developments, creditors and international financial agencies have worked closely with the Government in developing new repayment schedules. During fiscal year 1976-77, several private loans were obtained, including an $850 million loan arranged by Morgan Guarantee Trust and two loans totaling $200 million from Japanese banks; $1.5 billion worth of foreign credits was provided through Bank Negara Indonesia. Because of the Pertamina problem and an initial unfavorable U.S. IRS ruling affecting international investors in oil,[17] the Government started to revise the longstanding production-sharing contract system and looked for areas to net Indonesia more income. As a result, exploration activities hit rock bottom at the beginning of 1977.

Subsequently, the Government, realizing the concern it had created in renegotiating oil contracts and noting that the former IRS ruling had been reversed, took steps to provide incentives to investors to encourage renewed interest in exploration. The first actions taken in spring of 1977 were related

Digitized by Google

to "new" oil: Oil provided to Pertamina for domestic consumption will be measured at the prevailing market price for the first 5 years of production; a tax credit of 20% of the capital investment cost for new fields may be taken by the contractor from gross production before tax deduction; and for all new oil investment schemes, the 7-year accounting method will apply. Individual incentives were also given to Caltex, Aquitaine, Shell International, and Mobil. By late 1977 and early 1978, oil exploration started to pick up. Caltex began a $78 million enhanced recovery program. IIAPCO and Arco initiated development work in their Java Sea areas and made plans to quickly install new platforms. Total Indonesie plans to bring in new production shortly and had budgeted $50 million for exploration for the coming year. Stanvac plans to sign a new regular production-sharing contract for a central Sumatra area. Additional drilling will be done in Irian Jaya. Increased exploration in 1978, however, may mean that oil production will fall below the 1977 level.

Caltex's giant Minas Field in Sumatra continued to produce at about 350,000 barrels per day in 1977, compared with 770,000 barrels per day for the company as a whole and less than 100,000 barrels per day for its second-ranking field, Bangko. However, Caltex's overall output may decline as much as 130,000 barrels per day in the coming year, based upon the prognosis of 1977. Arco's four producing structures off the northwestern coast of Java, known as the Arjuna Fields, together furnished 104,000 barrels per day. Total Indonesie's Handil Field produced 180,000 barrels per day in 1977, and its Bekapai Field produced 50,000 barrels per day. IIAPCO's large Cinta Field produced 117,000 barrels per day during the year, and Union Oil's large Attaka Field produced 115,000 barrels per day. Petromer Trend's fields on the Vogelkop Peninsula of Irian Jaya were together producing about 80,000 barrels per day in 1977, with the Walio Field scheduled to boost overall output considerably.

At yearend, Indonesia's oil-refining capacity stood at about 530,000 barrels per day. Three refineries were in the 100,000- to 110,000-barrel-per-day range—Pladju in South Sumatra, Cilacap in Central Java, and Dumai in central Sumatra. Three refineries were in the 50,000-barrel-per-day range—Sungei Gerong in South Sumatra, Balikpapan in Kalimantan, and Sungei Pakning in central Sumatra. There were two smaller refineries called P. Brandan and Wonokromo. All of Indonesia's eight refineries are run by Pertamina as State operations.

The Mineral Industry of Iran

By Janice L. W. Jolly[1]

Iran's mineral production contributed approximately 38% of the Iranian year 1977[2] gross national product (GNP) of $75.3 billion[3] at current prices. Iran's economy continued to reflect the effects of the post-1973 oil boom, but the level of activity was lower as oil exports and domestic investment declined. Real GNP growth for Iranian year 1977 at constant 1974 prices was 0.9%, compared with 11.1% in Iranian year 1976. High inflationary rates were eroding growth and discouraging domestic investment. Static oil receipts and the consequent loss of purchasing power were negative factors in the country's growth. Nevertheless, expansions were planned and were well underway for the copper, aluminum, iron and steel, lead-zinc, cement, and natural gas industries.

Iran's sixth development plan (1979-83) was not yet available, but it was reportedly related to a 20-year national objectives scheme of which it was the first 5-year segment. Sector growths projected through 1983 were 27.2% for the oil and gas industries and 24.7% for mines and other industry.

Foreign investment in Iran was apparently increasing. Stimulating factors included the increasing market size and the necessity to produce inside Iran's protective walls. Relative political stability was also a criterion. The estimated value of all private foreign equity investment in Iran by August 1977 was $1.8 billion, to which the United States had contributed $700 million. Japanese investment in petrochemicals was expected to vastly increase this value in the near future.

PRODUCTION AND TRADE

The estimated mineral production value for Iranian year 1977 (based on average world prices) was $450 million, excluding petroleum products, natural gas, and clays. Mineral production included cement ($128 million), coal ($63 million), zinc ($53 million), chromite ($32 million), iron ore ($31.5 million), lead ($27 million), copper ($7.8 million), barite ($5.4 million), turquoise ($1.3 million), and gypsum ($33,000). Aluminum produced from imported alumina was estimated at $48 million. Crude petroleum production for Iranian year 1977 was valued at approximately $21 billion, natural gas production at an estimated $650 million, and petrochemicals production at an estimated $900 million.

Total nonpetroleum exports (which includes natural gas) were valued at $703 million for Iranian year 1976. Mineral ore exports, forming 2.8% of the total, were valued at $20 million, a decrease of 36% from those of Iranian year 1975. Exports of iron and steel products, on the other hand, increased 200% and were valued at $15 million.[4] Total nonpetroleum exports for Iranian year 1977 were valued at $524 million. Gas delivered by way of the IGAT-II pipeline to the U.S.S.R., valued at $195 million, accounted for 30% of the total gas produced for consumption in Iranian year 1977. An agreement was signed between the U.S.S.R. and Iran to increase natural gas deliveries 30%.

During Iranian year 1977, Iran exported 1.8 billion barrels of crude oil. Of this total, the Oil Service Co. of Iran (OSCO) trading companies exported 1.2 billion barrels (down 17.1%). National Iranian Oil Co. (NIOC) direct exports were 414.5 million barrels (up 32.5%), and NIOC joint venture exports were 196 million barrels (up 17.8%). During Iranian year 1977, 77,240,000 barrels of crude (down 0.2%) was delivered to

Digitized by Google

the Abadan refinery for refining and subsequent export by OSCO. NIOC exported about 7,838,200 barrels of refined products in the period August through December 1977.

The posted price for Iranian crude oil was $13.77 per barrel for 34° API gravity crude and $13.43 per barrel for 31° API gravity crude in January 1977.[5] Demand for Iranian heavy crude remained low, and the price was cut 9.5 cents per barrel at midyear. Major importers of Iranian crude were Japan (17%), Carribean and West Indies countries (12%), the Netherlands (8%), the United States (8%), and the Republic of South Africa (6%).

[e]Estimate. [p]Preliminary. [r]Revised. NA Not available.

[1]Data are for the Iranian calendar year, which is the year beginning March 21 of that stated, except data for natural gas, natural gas liquids, and petroleum, which are for regular calendar years.

[2]In addition to the commodities listed, other types of crude construction materials (such as common clays, sand and gravel, and other varieties of stone) are also produced, but output is not reported and available information is inadequate to make reliable estimates of output levels.

[3]Excludes petroleum produced and reinjected into fields.

Table 2.—Iran: Exports of mineral commodities[1]

(Metric tons unless otherwise specified)

Commodity	1975	1976	Principal destinations, 1976
METALS			
Aluminum metal including alloys, all forms	[r]15,545	1,508	Japan 1,506.
Arsenic, natural sulfides	4	5	All to Bahrain.
Chromium: Chromite, 48% Cr_2O_3	77,078	5,400	Yugoslavia 5.
Copper:			
Ore and concentrate	8,700	4,200	All to Japan.
Metal including alloys	[r]3	6	Saudi Arabia 5.
Iron and steel:			
Ore and concentrate	220	214	Sweden 144; Iraq 70.
Metal:			
Pig iron, ferroalloys, similar materials	85	161	Iraq 150.
Semimanufactures	3,600	1,563	Saudi Arabia 833; Hungary 316; Kuwait 181; Afghanistan 161.
Lead:			
Ore and concentrate	82,382	4,444	Mainly to U.S.S.R.
Metal including alloys, all forms	7	--	
Silver waste and sweepings, troy ounces	6,559	31,893	Libya 27,617; United States 4,276.
Zinc ore and concentrate	63,308	32,765	U.S.S.R. 14,515; Poland 10,000.
Other ores and concentrates	[r]1,000	--	
NONMETALS			
Abrasives, natural:			
Crude, n.e.s.	--	600	All to Kuwait.
Grinding and polishing wheels and stones	[r]26	676	Kuwait 442; Romania 220.
Cement	1,169	--	
Chalk	20	40	Afghanistan 20; Greece 20.
Clays and clay products:			
Crude:			
Kaolin	(2)	10	Italy 9; West Germany 1.
Fuller's earth	9	4	All to Bahrain.
Fire clay	3	--	
Drilling mud	10	--	
Other	[r]2	1	Mainly to India.
Products:			
Refractory	39	10	All to Kuwait.
Nonrefractory	[r]31	687	U.S.S.R. 588; Bahrain 96.
Diamond, value	$29,949	--	
Fertilizer materials:			
Manufactured:			
Potassic	[r]354	21	All to Kuwait.
Other	2,962	3,075	Kuwait 1,860; Abu Dhabi 604; Oman 484.
Ammonia	67,195	9,151	Mainly to United States.

COMMODITY REVIEW

METALS

Aluminum.—Iran had no known commercial bauxite deposits and was therefore pursuing a course that included importing alumina for domestic processing, investigating the use of extensive domestic alunite deposits, and assisting in the development of nearby foreign bauxite deposits such as those in India. The current demand for alumina was about 90,000 tons per year; this was expected to rise to 950,000 tons by 1988.

Iranian Aluminium Co. (Iralco) was a joint venture between the Iranian Government Industrial Development and Renovation Organization (IDRO) (82.5%), the Pakistani Government (5%), and Reynolds International (12.5%). Construction of the plant at Arak was completed in 1973. Alumina was imported from Australia and India for use in the Iralco plant. The alumina was bulk-delivered by ship to Bandar-e Shahpur, where it was transferred into special 50-ton railcars for the 650-kilometer trip to Arak. Electric power was the most important initial consideration for situating the alumina plant at Arak. Hydroelectric power was available from the Reza Shah Dam, located 300 kilometers away, and later gas was piped in. In Iranian year 1976, however, the Arak plant produced at only 84% of capacity because of an electric power deficiency. The capacity of the smelter was being expanded to 125,000 tons per year by 1980, but this was dependent upon the availability of additional sources of energy to be furnished by gaslines under construction.

An agreement with Aluminum Co. of Canada Ltd. (Alcan) was signed on May 19, 1977, for the construction of a second aluminum smelter at Bandar 'Abbas. Alcan was awarded a $2.5 million contract to undertake the feasibility study for the new smelter. Iran's alunite deposits, estimated at 1 billion tons at Takestan in East Azerbaijan Province, were under consideration, but alumina from foreign sources would most likely be used for the new plant.

As a potential source of alumina for Iran's expanding aluminum industry, a trade protocol was signed with India for the development of bauxite in Andhra Pradesh and Orissa States of India. Extensive bauxite reserves had been located, and the Indians were looking for foreign partners to establish alumina plants in the area.[6]

It was reported that Iran and the U.S.S.R. had signed an agreement for a $600 million alumina plant in Tehran with an initial 500,000-ton annual capacity and a provision to double this figure. A study was being undertaken to determine the feasibility of using alunite for this plant.

Chromite.—In 1977, chromite was being produced from mines in three districts. In the northeastern Froumad District, Froumad Chromite Mining Co., owned 51% by Iran Mining and Metallurgical Co. (IMMC), was operating the Gaft mine. In the Esfandagheh District of southern Iran, the Abdasht and Bahborj mines were operated by Esfandagheh Mining Co., owned by IMMC (2%), Resai Bros. and other private Iranian interests, and British Engineer and Planning Resources Corp. The Amir and Shahriar Shahin mines of the Fariab District near Minab were the largest producers and were being operated by Fariab Co., owned by the Shahriar Industrial Group and Philipp Bros. (Canada) Ltd. Approximately 233,300 tons of chromite was produced in Iranian year 1977.[7]

Copper.—Copper reserves in active mines were estimated at over 1 billion tons, including new reserves added at Sar Cheshmeh through deep drilling in the open pit[8] (bringing the total to 850 million tons of 1.2% copper) and at the mine at Qal'eh Zari (adding 200 million tons of 3% to 4% copper). Estimated reserves at several smaller mines included 300,000 tons at Mazra'eh, located west of Razan; 100,000 tons at Baychebagh, located west of Mīaneh; and 200,000 tons at Chiezeh, located south of Rasht.

Mining at the Qal'eh Zari mine began in 1975 by Minak Co., a Japanese-Iranian joint venture of Toho Zinc Co., Ltd., Ataoka Sangya, and the private Iranian firm Sherkat Sahami Maaden Loute. The mine, located south of Birjand in southern Khorāsān Province, was being mined by underground methods. The entire production of about 14,000 tons per year of 30% copper concentrate was being exported to Japan.

Copper ore was being stockpiled at Sar Cheshmeh awaiting completion of the concentrator and smelter complexes. Concentrator production was expected to start in August 1978 and smelter production soon thereafter. Construction of the related township, known as New City, was far behind, plagued by a shortage of skilled labor. Concentrator capacity was to be

Digitized by Google

40,000 tons per day of ore with a head grade of 1.2% copper. The following equipment was included in the crushing and grinding sections: Primary crushing—a Fuller 10.5-foot gyratory crusher of 4,200-ton-per-hour capacity; secondary crushing—three Nordberg standard-cone crushers; tertiary crushing—six Nordberg shorthead-cone crushers; and wet grinding—eight 8-meter-long by 5-meter-diameter ball mills.

National Iranian Copper Industries Co. awarded Krupp Industrie- und Stahlbau of the Federal Republic of Germany and Mechim of Belgium contracts totaling $143 million for engineering and procurement at Sar Cheshmeh. Krupp and Mechim hold 45% and 55%, respectively, in the consortium. Mechim was to undertake technical coordination and Krupp was to be overall manager for the project. The contracts included a copper refinery with an annual capacity of 158,000 tons of electrolytic copper, a nickel sulfate plant, and a facility for recovering various precious metals. Construction under the Krupp-Mechim contracts was to begin in early 1978, and the complex was expected to come onstream in 1981. Until the refinery starts up, all copper was to be exported to European refineries. The total cost of the Sar Cheshmeh mine and processing plant was put at $1.12 billion, and the township and related facilities were estimated at another $2.3 billion. By-product molybdenum was expected to add another $100 million to $150 million of earnings per year, based on a full production of 3,000 tons. The Anaconda Company (United States) technical service and consulting contract signed in 1974 was to last 10 years.

The Iranian Geological Survey was undertaking a 3-year, $29 million exploration program along the Iranian copperbelt that extends through Baluchestan, Kermān, and Yazd Provinces. New copper mines were under development at Meiduk near Kermān, and deposits located at Chehelkareh in the Zahedan area of Baluchestan Province were being explored by Minak.

Gold.—Approximately 100,000 tons of gold ore had been mined at the Muteh gold mine and was ready for further processing. Production had been suspended since 1972. IMMC signed an agreement with IDRO to establish a gold-casting factory. IMMC was to build a 200-ton-per-day concentrator and a cyanide plant at the Muteh mine, located south of Qom. Further exploitation of the Muteh gold-pyrite-quartz vein deposit was included in the fifth development plan objectives. Reserves were estimated at 500,000 tons averaging 0.2 troy ounce of gold per ton, with probable reserves of 2 million tons.[9] Exploration was being carried out around the Muteh mine and throughout the district. There were approximately 50 other gold-bearing properties for which further detailed exploration was planned.

Iron Ore.—Iron ore was produced by National Iranian Steel Corp. (NISC) from the Choghart deposit located in the Bafq District west of Yazd. The Bafq District was estimated to have nearly 600 million tons of magnetite-hematite reserves with up to 65% iron distributed in several deposits. This included 170 million tons at the Choghart deposit, 150 million tons at the Northern Anomaly, 150 million tons at Anomaly XI, and 100 million tons at the Chadar Malu deposit. All of these deposits were scheduled for further development. Ore from the Choghart deposit was used to supply the Aryamehr steel plant at Isfahan, which was also operated by NISC.

Reserves at the Gol-e-Gowar iron ore deposit located in the Kermān area were estimated at 400 million tons with 60% iron and a comparatively low phosphate and sulfur content. This mine was being developed by National Iranian Steel Industries Co. (NISIC) and Grängesberg Industriavaru AB of Sweden. Production from Gol-e-Gowar was expected to reach 5 million tons per year by 1980. Also slated for development by NISIC under the sixth development plan were the iron ore deposits at Tangezagh, 150 kilometers south of Gol-e-Gowar near Bandar 'Abbas, estimated to contain 60 million tons of 56% to 62% iron.

The Arak District in west-central Iran also had several deposits of iron ore, the largest of which was at Shamsabad with an estimated 100 million tons of limonite-hematite ore averaging 43% iron. There were no announced plans to develop these deposits. Total resources of iron ore in Iran were estimated at about 1.6 billion tons.

Iran was financing the development of the Kudremudkh iron ore deposit in India. Of the total $630 million Iranian loan, $450 million was to be spent on the mine and processing plant, $90 million for a mineral port at Mangalore, $70 million for power facilities, and $20 million for townsites. Iran was to import much of this ore for use in its steel mills.

Iron and Steel.—Iran expected to produce 6.7 million tons of steel by 1982. This was somewhat below the expectations of the fifth development plan, which had a goal of 10 million tons of steel to be produced by the end of the plan period in 1978. To

Digitized by Google

achieve this, the Government embarked on a program of expansion that included new mills using direct-reduction. The Soviet-built NISC steel mill at Isfahan used conventional technology. Most of the direct-reduction plant projects, which will utilize abundant local natural gas resources, were to be built and operated by the Government organization NISIC. Three of the seven planned steel mill projects were expected to be producing by 1983. These plants were to be located at Ahwaz, Bandar 'Abbas, and Isfahan and were expected to consume about 5.2 million cubic meters of gas per year. Iran's steel consumption was expected to reach 6 million tons by 1978, and predictions were that consumption would reach 12 million tons by 1982.

The first steel mill project completed by NISIC started production in mid-January 1978. This was the first unit (Purofer plant) of the Pahlavi steel complex at Ahwaz. The Ahwaz steel complex was to have a capacity of 2.8 million tons of steel per year and was to have three direct-reduction mills, each with a different process. One mill with a 1.2-million-ton-per-year capacity was to use the Midrex method; another with a 1-million-ton-per-year capacity was to use the HyL method of Pullman Swindell Corp. of the United States; and the third with a 400,000-ton-per-year capacity was using the Purofer method suppled by Thyssen Rohrenwerke A.G. The total investment at Ahwaz was estimated at $800 million. A trial operation of the prototype Purofer process began in early 1977. The plant produced 30,000 tons of sponge iron briquets in its first month.

In early 1977, the basic design work for the Bandar 'Abbas steel plant was completed. Costruzioni Metalliche Finsider S.p.A. (Italy) was to direct the completion of this NISIC project, which would consist of direct-reduction furnaces with a total capacity of 3 million tons per year and would cost about $3 billion to construct. Finsider was to provide 20% and NISIC the balance of the $100 million initial capital for Bandar 'Abbas Rolling Mill Co. Terms also involved an oil barter deal, which was used to finance about 60% of the project. Construction on the complex was to begin in 1982. The NISIC steel project at Isfahan was to have an annual capacity of 1.2 million tons of sponge iron.

NISC's Aryamehr steel mill at Isfahan was producing 600,000 tons per year of various steel products. Expansion was underway to raise capacity to 1.9 million tons by the end of 1978. The plant's capacity was planned to eventually reach 6 million tons per year.

Lead and Zinc.—Approximately 37 lead-zinc mines were operating in Iran. The largest zinc producers were the Angouran mine, operated by Sherkat Sahami Calcimin, with 18% of total production; the Kushk mine, operated by Bafq Mining Co., with 12% of total production; and the Shahkuh mine, operated by Bama Private Co., with 7% of total production. Both the Angouran and Kushk mines were owned by Soc. Industrielle et Minière Iranienne (SIMIRAN), a private Iranian company that also owned the Ardokan and Shah-Ali Baglou lead-zinc mines. Construction of the concentrator at Angouran was completed in 1977, and the mill had a capacity of 2,000 tons of ore per day. The Kushk mine was being expanded to 40,000 tons per year of zinc ore and 10,000 tons per year of lead ore. Bama had contracted a Swedish group to complete electrical installation for two concentrating plants. Production from the first plant had already started. A crusher station, dense-media separation station, and flotation plant were included. Total capacity at the Shahkuh mine was expected to be 1 million tons per year of lead-zinc ore at the end of 1977.

Significant lead producers included the Ravandje mine, operated by Sogemiran S.A. (a subsidiary of Soc. Générale des Minerais S.A. of Belgium); the Nakhaluk mine, operated by IMMC; and the Mehdiabad mine, operated by Mehdiabad Mining Co. (a joint venture of Meshahr Mining Co. and AMAX Inc.). The Ahangaran open pit lead-zinc-pyrite mine located west of Arak near Malayer was operated by Sormak Mining Co. (a private Iranian firm). This mine had reserves indicated at 1 million tons of 10% lead, both as sulfide and carbonate. The concentrate was being sent to the U.S.S.R. for further processing. By early 1977, the mine was producing 300 tons per day of ore, which resulted in 30 tons per day of 50% lead concentrate.

Ore reserves reported for Mehdiabad, located south of Bafq, were 24 million tons of lead-zinc ore with some copper and silver. Also located near Bafq, the Kushk mine was estimated to have 10 million tons of lead-zinc ore. Shahkuh, located near Isfahan, had 6 million tons of lead-zinc reserves, and Angouran, located west of Rasht, had reserves of 6 million tons of zinc-lead ore.

Uranium.—Iran had budgeted $300 million for a 10-year exploration program for uranium as part of a program geared to expanding alternative means of energy production. A Peko-Wallsend Group member, Austirex Aerial Surveys, was to explore northwestern and eastern Iran in an air-

Digitized by Google

borne geophysical survey under a contract awarded by the Atomic Energy Organization of Iran (AEOI). The survey was to cover 290,000 square kilometers. A reconnaissance study was also to be made in the Makran and Zagros regions. Representatives of the U.S. Energy Research and Development Administration (ERDA) and AEOI were to meet periodically to discuss the Iranian exploration program. ERDA was to give short periods of training and provide advice on various technical aspects of the exploration program. Government geologists of the Federal Republic of Germany were also to aid in the development of uranium and thorium research and exploration.

The AEOI lost its mandate to plan, construct, and operate nuclear power reactors after the Iranian Parliament voted to expand the Ministry of Energy's charter to include these responsibilities. All activities related to nuclear power reactors were to be transferred to the Ministry of Energy.

Iran had plans to install 23,000 megawatts of nuclear power capacity within a 20-year period. To date, four plants with a combined capacity of 4,200 megawatts had been ordered and were under construction. Kraftwerk Union A.G. (KWU) was building two powerplants at Büshehr costing $3.3 billion. Iran was to exchange $270 million in crude oil for the two reactors. A Japanese group was providing the two water desalination units that were to be constructed next to the reactors. Électricité de France (EdF) was to install two 960-megawatt reactors on the Kārūn River near Ahwaz at a cost of over $2 billion. Negotiations for additional plants from these two countries and the United States were underway. Late in 1977, a letter of intent was signed with KWU for four nuclear plants including two at Isfahan and two at a site between Isfahan and Lake Rezaieh near the Turkish border.[10] Iran and the United States signed an agreement to share technical information related to nuclear safety and protection of the environment in April 1977. The United States was to provide two nuclear energy safety advisors through the U.S. Nuclear Regulatory Commission (NRC).

NONMETALS

Asbestos.—A major asbestos deposit was identified in southeastern Iran, 275 kilometers northwest of Zahedan.[11] Exploratory drilling was being carried out.

Barite.—Although there were a number of small deposits of barite in Iran and some byproduct production from lead-zinc mining, the bulk of the milled material was being produced by three companies. The privately owned Iran Barite Co. produces about 100,000 tons per year of barite, along with some lead, zinc, pyrite, and bentonite, from operations at the Semnān mine. Sherkat Sahami Magcobar Iran (a joint venture of Dresser Magcobar Corp. of the United States and SIMIRAN) mines barite from several underground operations at Keraj (35,000 tons per year), Vardeh (40,000 tons per year), Nobaran (20,000 tons per year), and Siahkuh (15,000 tons per year). Processing was being done at Parandak, where additional capacity was recently installed. Magcobar Iran was also hiring exploration geologists for an extensive industrial exploration program. Doreen-Imco Co. was recently formed to mine barite as a joint venture between Imco Services (U.K.) Ltd., a division of the U.S. firm Halliburton Co., and an Iranian mining company. Doreen-Imco was to operate a mine and grinding facilities near Keshan. A production capacity of 110,000 tons per year began in late 1977. The company employed 55 Iranian workers in the mine and plant.

Cement.—Cement was being produced by 12 plants in 1977, and 14 more were either planned or under construction. Cement production was expected to reach 20 million tons by 1980. Annual capacities of the operating plants were as follows: Tehran, 2,340,000 tons; Abyek (or Qazvin), 2,100,000 tons; Doroud, 1,350,000 tons; Shiraz (or Fars), 900,000 tons; Suffian, 800,000 tons; Loshan (or Sefid Rud), 720,000 tons; Kermān, 700,000 tons; Isfahan, 650,000 tons; Meshed, 560,000 tons; Rey, 150,000 tons; Ghani Abad, 100,000 tons; and Djadjerud, 30,000 tons. Plants with the following annual capacities were under construction: Isfahan (or Aryamehr), 2,000,000 tons; Behbehan, 800,000 tons; Tabrīz, 800,000 tons; Māzandarān, 720,000 tons; Kermānshāh, 660,000 tons; and Gorgan (or Neka), 600,000 tons. In addition, IDRO was planning to build cement plants with the following annual capacities: Bandar 'Abbas, Chak Behar, Kashan, and Reza'iyeh, each 720,000 tons; Hamadan, 700,000 tons; and Sanandaj, Yazd, and Zahedan, each 360,000 tons.

Production of cement amounted to about 6.1 million tons compared with a demand of around 7 million tons for Iranian year 1976. It was anticipated that the majority of new plants will start operation in the next 2 years. The Blue Circle Group of the United Kingdom was awarded the contract for design and supervision of the $91.3 million

Digitized by Google

cement plant at Hamadān. Construction was to begin in early 1979. The cement plant at Suffian was being expanded to 3,600 tons per day (1.3 million tons per year). In 2 1/2 years, the Suffian plant is to add another 2,000-ton-per-day unit.

Clays.—Two companies account for most of Iran's bentonite production. Iran Barite produces 30,000 tons per year of bentonite and other clays from mines at Hehrejan, Semnān, and Zarrin. Magcobar Iran produces 15,000 tons per year from the Grimonj deposits.

Fertilizer Materials.—*Phosphate Rock.*—The French Bureau de Recherches Géologiques et Minières (BRGM) signed a contract with the Iranian Government for phosphate exploration in 80,000 square kilometers on the border of the Persian Gulf in Khorāsān Province.[13]

Stone.—*Limestone.*—Limestone for use in the sintering plant at the Aryamehr steel mill came from Pirbakran (Isfahan Province). About 65,000 tons of limestone was produced for use at the Aryamehr steel refractory plant.

MINERAL FUELS

Coal.—The Aryamehr coke-oven and byproducts facility at Isfahan consisted of six plants, including a coal-handling plant, a coke-oven battery, a byproduct sulfuric acid plant, a benzol distillation plant, and a coke test station. The main function of the coke-oven facility was to produce coke for use in NISC's Ayramehr steel plant blast furnace. The coke was also used as fuel in the sintering foundry, in various chemical industries, and in the production of various nonferrous metals. Coke gas was also produced and used to heat the coke-oven battery and as fuel in most steel plant shops. Coal was supplied from local mines operated by NISC, such as the Shāhrūd, Sanghroud, and Zirab mines in the Alborz region and the Pabdedana and Babnizoo mines in Kermān Province. Production of dry coke was estimated at 444,000 tons in Iranian year 1977. Proved coal reserves were estimated at 600 million tons and probable resources at as much as 25 billion tons.[13]

Natural Gas.—Included in the $8 billion, 5-year Government budget for natural gas development by the 1980's was the second gasline, IGAT-II, to the U.S.S.R. and a third gasline to western Iran. Iran was planning to extinguish all gas flares by 1980. Plans also included development of several gasfields, including the Pars and Khangiran gasfields, with as many as 180 wells for gas injection, expansion of natural gas liquids (NGL) facilities, and construction of new liquefied natural gas (LNG) projects. Assuming completion of current projects, Iran was expected to have an export capacity of about 67 million cubic meters of gas per year by the mid-1980's.

Iran's proved natural gas reserves were estimated at over 16 trillion cubic meters. The offshore Pars field (formerly known as the C Structure) in the Persian Gulf was estimated to have gas reserves of 5.7 trillion cubic meters. Proved reserves of associated gas in the Khūzestān fields were estimated at 8 trillion cubic meters. The Khangiran field was estimated to contain over 500 million cubic meters of proved gas reserves. Natural gas reserves found in the Aghar, Gavarzin, Kangan, Nar, Salakh, Sarkhun, Suru, and other smaller fields constitute the remainder.

Plans were proceeding for development of the Pars gasfield, including a floating LNG plant that would be used to liquefy gas for export to the United States. Kvaerner Engineering A.S./Moss Rosenberg Verft A.S. (Norway) was to supply the plant, which would produce some 8.5 million cubic meters per day of LNG to be sold to Columbia Gas System Inc. of the United States under a 20-year contract. The LNG plant, terminal, and an onshore gas treatment plant were to cost about $830 million. Deliveries were scheduled to start in early 1980.

The longest running project planned to use Pars field gas was the Kalingas plant, which would export LNG to Japan. The initial participants were National Iranian Gas Co. (NIGC) (50%), Japan Kalingas (a group of 18 Japanese companies) (15%), International Systems & Controls Corp. (United States) (15%), Halfdan Ditlev-Simonsen & Co. (Norway) (7.5%), Chicago Bridge & Iron Co. (United States) (7.5%), and Enserch Corp. (United States) (5%). Following a complex series of transfers in ownership, all of NIGC's partners except Japan Kalingas and Chicago Bridge & Iron dropped the project. This left NIGC with 82.5%, Japan Kalingas with 15%, and Chicago Bridge & Iron with 2.5%. At the same time, the project was cut to around 10 million cubic meters per day. By late 1977, it appeared that Japan Kalingas would withdraw from the project and instead go ahead with another 50-50 LNG joint venture with NIGC. The remaining partners of Japan Kalingas were to implement a floating LNG plant system.

The new Japan Kalingas project included construction of an onshore liquefaction

Digitized by Google

plant that would produce 2.5 million tons of LNG per year for export to Japan over 20 years, beginning in 1982. The total investment required was estimated at $1.9 billion, divided between LNG facilities ($767 million), five LNG carriers ($767 million), and terminal facilities in Japan ($384 million).

Soviet, Italian, and French groups were given contracts to build the IGAT-II gasline, which was to extend 1,420 kilometers from the onshore Kangan and Nar gasfields in southern Iran to Astara on the Soviet border. Work was to begin in 1978, with deliveries starting in 1981 and reaching target capacity by 1983. Planned on a larger scale than IGAT-I, which carries about 10 billion cubic meters of gas per year to the U.S.S.R., IGAT-II was to have a capacity of 28 billion cubic meters per year. Up to 31 million cubic meters was to be used in Iran's northern cities. The French group Spie-Batignolles/Capag-Cetra and the Italian firm Saipem S.p.A. were to construct sections of the line. The project was to cost about $2.4 billion. Payment for the gas would be in Soviet ruble credits that would be used to pay for Soviet construction of the northern section of the pipeline. The U.S.S.R. was also expected to provide most of the compressor stations under a gas barter deal.

The Kangan and Nar gasfields were to be developed by a European consortium headed by Elf-Aquitaine. The European Group of Oil Companies (EGOCO) was dissolved, and a new company, Segiran, was formed in which Elf-Aquitaine had a majority interest as a joint venture with NIOC. These fields were originally discovered by EGOCO.

NIOC was optimistic about planned gas reinjection programs because of successful results at the Haft Kiel and Gachsaran fields. Since mid-1976, about 11 million cubic meters of gas from the Naft Safid oilfield had been injected at Haft Kiel, and wet gas from the Pazanan gas domes was injected into the Gachsaran oil reservoir. The Marun field was to be next in early 1979. Contracts for gas reinjection from the Pazanan field were awarded, and the first of two facilities was scheduled to supply gas for Gachsaran by mid-1978.

Industrial development in northern Iran was to be bolstered by the 800-kilometer, 30- and 36-inch gas transmission system under construction to serve steel mills and petrochemical plants. The pipeline will transport gas from the Khangiran gasfield in Khorāsān Province to the Neka powerplant, which was under construction on the southern shore of the Caspian Sea in Māzandarān Province. The project included a gas-gathering system, a gas-treating plant, the pipeline, five compressor stations, a supervisory control system, a telecommunications system, and cathodic protection.[14]

A gas-processing facility with a 2.8-million-cubic-meter-per-day capacity was to be built at Gorzin on Qeshm Island and connected by undersea pipeline to Bandar 'Abbas. Production would be piped overland to industries in Kermān Province.

The Marun field was being developed to produce associated gas using 27 turbine-driven, single and tandem, natural gas compressor sets for gas gathering and transmission to be installed by Ralph M. Parsons Co. of the United States. The specially designed Solar Centaur compressors were to be located at seven sites in the field. The 23 tandem sets were to take gas off separators and pump it to pipeline pressure to NGL plants. The 4 single-body units were to deliver lean gas from the plant to feed the liquefied petroleum gas (LPG)-petrochemical installation being built by a consortium of Iranian and Japanese companies.[15]

Petroleum.—*Exploration.*—NIOC held exploration service contracts with several companies, but there was a general decline in exploration activities during 1977.[16] Even so, OSCO continued an active exploration program, increasing the number of seismic crews to six and conducting an active exploration program with an average of 14 drilling rigs for the year.

Deminex A.G. of the Federal Republic of Germany continued prospecting with some hope of initiating commercial production from the reservoir it had discovered on the Abadan Plain. Abadan crude was low-gravity and was expected to face marketing difficulties. An evaluation program was in progress. NIOC's own exploration was also active, with most efforts concentrated on the Sarveston oilfield near Shiraz.

France's Cie. Française des Pétroles (CFP) was expected to relinquish its 8,000-square-kilometer area in the Lar region. CFP drilled two dry holes in the prospecting area, located inland in southern Iran. Continental Oil Co. (Conoco) also relinquished its 25% share in the Bandar 'Abbas offshore exploration tract that it shared with Phillips Petroleum Co. Iran (50%) and Cities Service Co. (25%). Eight wells had been drilled since 1969, but no commercial discovery was made.

Sofiran had essentially ceased its exploration program but was preparing to produce from two of several small offshore discoveries near Hormuz. Negotiations with NIOC on its basic operating agreement

Digitized by Google

were still in progress. Hormoz Petroleum Co. (HOPECO), owned by NIOC 50%, Petróleo Brasileiro S/A (PETROBRAS) 25%, and Mobil Oil Corp. 25%, was also exploring in the Strait of Hormuz and had some success. Iran Pan American Oil Co. (IPAC), Lavan Petroleum Co. (LAPCO), Soc. Irano-Italienne des Pétroles (SIRIP), and Iranian Marine International Oil Co. (IMINOCO) had all ceased exploration efforts.

Production.—Petroleum production for Iranian year 1977 averaged 5.7 million barrels per day, down slightly from the 5.9 million barrels per day produced in Iranian year 1976. OSCO's production reached 6.1 million barrels per day in the final quarter of 1977, but demand for Iranian crude was soft in early 1977 and production was at a lower pace. Most crude was exported, but domestic consumption was estimated at 450,000 barrels per day. Iran's domestic consumption was estimated to reach some 1.2 million barrels of crude oil per day by 1988.[17] Production in 1988 was being forecast to peak at 6 million barrels per day, down from the previous estimate of 7.6 million barrels per day.

Proved crude oil reserves were estimated at 65 billion barrels,[18] with most of the latest increase resulting from the gas injection program. NIOC reserve estimates run as high as 90 billion barrels, with about 20 billion barrels added from the secondary recovery program.

Much of Iran's crude oil contains salt in excess of the 11-pound-per-1,000-barrel limit placed on oil to be exported. Iran was planning to install over 2.8 million barrels per day of crude oil desalting capacity by 1981. Desalting facilities were to be built in about a dozen fields, including plants for two different reservoirs in the Ahwaz field. The desalting capacity added was expected to represent a large share of the country's oil production in the future.[19]

IPAC was producing petroleum from four fields. The Ardeshir field, which began production in November 1976, had reached 200,000 barrels per day and was IPAC's largest producing field. The Feridoun field (160,000 barrels per day) accounted for 44.6% of IPAC's total production in Iranian year 1977. The Darius and Cyprus fields had production capacities of 70,000 and 35,000 barrels per day, respectively.

LAPCO produced about 66.5 million barrels from its Sassan field in Iranian year 1977. The Bahram field (formerly the W Structure) was thought to have a potential of 50,000 barrels per day and was still being developed. A 14-inch oil line was extended to a new 1-million-barrel storage tank at the Lavan Island terminal, but a final decision had not been reached between NIOC and its LAPCO partner on development terms. LAPCO's productive capacity was also being increased by a secondary (waterflood) recovery project at the Sassan field.

The Khūzestān fields, operated by OSCO as an NIOC contractor, accounted for 90.1% of total Iranian year 1977 production. Development drilling was continuing at high levels but was expected to decline because of other major investments required for gas injection and desalting programs. Total new and expanded capacity was 460 million barrels per day. Despite completion of new facilities (including new production units, desalting plants, main oil lines, additional pumping capacity, etc.), there was a drop in productive capacity of the Khūzestān fields during 1977, caused mostly by a drop in reservoir pressures and the need to shut in numerous wells because of salt contamination. Capacity was expected to recover, however, to a level of 6.2 million barrels per day in Iranian year 1978 as desalting and gas-lift systems are commissioned.

The IMINOCO joint venture (NIOC 50% and Agip S.p.A., Phillips, and the Oil and Natural Gas Commission of India each 16.67%) produced oil from the Rostam and Rakhsh fields near Lavan Island. Total production from these two fields was 16.7 million barrels in Iranian year 1977.

SIRIP was the oldest of the Iranian oil-producing joint ventures with NIOC and produced from three fields northwest of Kharg Island. Total production capacity was about 55,000 barrels per day.

Sofiran (owned by Entreprise de Recherches et d'Activités Pétrolières (ERAP) 40%, Mitsubishi Oil Development Co., Ltd., 40%, and Soc. Nationale des Pétroles d'Aquitaine (SNPA) 20%), on the basis of a 1966 service contract agreement with NIOC, was preparing to begin production from the offshore Sirri C and Sirri D Fields. Facilities were installed to inject water during the initial phase of production. Commercial production was to begin during 1978 at about 50,000 barrels per day, later increasing to 100,000 barrels per day.

Refining.—Refineries at Abadan, Tehran (I and II), Shiraz, and Kermānshāh processed a total of 280.1 million barrels of crude oil in Iranian year 1977. The new crude distillation unit was completed at the Abadan refinery, bringing its throughput capacity to 600,000 barrels per day. Refineries were under construction at Isfahan (73 million barrels per year) and Tabrīz (29

Digitized by Google

million barrels per year), and a refinery for Ahwaz (80 million barrels per year) was in the planning stage. The Masjed-e-Soleman topping plant processed only about 6.7 million barrels of crude oil in Iranian year 1977, and the Lavan topping plant processed 4.3 million barrels.

Iran's domestic distribution system was continuing to expand with several new petroleum products pipelines added, including those extending from Isfahan to Tehran, Ahwaz to Abadan, Tehran to Shāhrūd, Shāhrūd to Meshed and Gombad, Tabrīz to Reza'iyeh, Tehran to Rasht, Tehran to Sārī, and Marun to Isfahan. A new 550,000-barrel-per-day pipeline to carry crude from the Marun fields to a new refinery at Isfahan was nearing completion. The project was a joint effort of SNAM Progetti S.p.A. and Saipem of Italy. Moody International was to supervise construction of 26 storage tanks adjacent to the refinery. The largest tank capacity was to be 258,000 barrels.[20]

Petrochemicals.—Since the establishment of the Shiraz fertilizer complex in 1961, five additional petrochemical facilities have been completed by National Petrochemical Co. of Iran (NPCI) and its joint ventures. Existing facilities include those of Iran Fertilizer Co., which produces urea, ammonium nitrate, soda ash, sodium bicarbonate, and fertilizers; Abadan Petrochemical Co. Ltd. (NPCI 74% and B.F. Goodrich Iran S.A. 26%), which manufactures plastics and detergent raw materials; Shahpur Chemical Co. Ltd., which manufactures phosphoric fertilizers with imported phosphate rock and domestic sour natural gas (25% H_2S); Kharg Chemical Co. Ltd. (NPCI 50% and Amoco Iran Oil Co. 50%), producing propane, butane, and gasoline; Iran Carbon Co. (Cabot Corp. 50%, NPCI 20%, Industrial Mining and Development Bank of Iran 10%, International Finance Corp. 10%, and private interests 10%), which produces carbon black; and Iran Nippon Petrochemical Co. (INPC) (NPCI 50%, Mitsubishi Chemical Industries Ltd. 24%, and Nissho-Iwai Co., Ltd., 26%), which produces phthalic anhydride and DOP plasticizer. Phase 1 of the INPC plant was operational, and phase 2 was in an advanced stage of planning.

In 1977, the petrochemical industry had a capacity of nearly 3 million tons per year of petrochemical products. Several new plants were being constructed or planned. Iran Japan Petrochemical Co. Ltd. (IGPC) (NPCI 50% and Iran Chemical Development Co. 50%) was constructing a complex at Bandar-e Shahpur that included a salt-electrolysis plant for caustic soda and chlorine gas, an olefin-cracking plant, and a benzene and xylene plant. The complex was expected to cost $1.8 billion.

The Mineral Industry of Iraq

By David E. Morse[1]

The petroleum industry continued to dominate the Iraqi mineral sector, and the country maintained its position as the third largest Middle East oil producer in 1977. Iraq had a signficant and growing cement industry and substantial production of sulfur, and also produced salt and construction materials for domestic consumption.

In June 1977 after a delay of almost 2 years, Iraq announced its 1976-80 5-year development plan. Allocations for projects under the plan totaled $45 billion,[2] of which $13 billion had been allocated through 1977. Under the plan, the growth rate of the gross domestic product (GDP) was to be 17% per year. The plan emphasized human development to meet Iraq's growing need for skilled manpower without importing large amounts of foreign labor. It provided for large-scale expansion of vocational, technical, and university-level training programs. It was to improve medical services, housing, and educational facilities for all levels of Iraqi society.

The plan sought to alleviate the economic constraints imposed by the nation's overburdened transportation, communications, and distribution systems and by its limited electrical generation capacity. Allocations under the plan for railroad and road construction were in excess of $3 billion. Nearly $2.2 billion was to be spent to increase electricity generation capacity from 950 megawatts to 4,000 megawatts by 1980. Iraq was also expanding its electricity distribution system by adding more 132-kilovolt supply lines and implementing a computer-managed 400-kilovolt national grid.

Iraq's major port of Basra on the Shatt al Arab was to be expanded and significant new port facilities were to be built on Khor al Zubair (the Zubair estuary). Khor al Zubair was dredged to accomodate ships of up to 60,000 deadweight tons and was to handle large bulk shipments for the new steel and fertilizer complexes and facilitate exports of sulfur and phosphatic fertilizers from northern Iraq.

In 1977, Iraq's economy continued to expand, with the GDP reaching $19 billion, an 18% increase over the 1976 level. The petroleum sector's contribution to the GDP decreased from 60% in 1974 to approximately 50% in 1977.

PRODUCTION AND TRADE

There was very little change in mineral production in Iraq in 1977, but progress was made on new facilities to expand mineral industry output by the end of the decade. Crude oil production declined to 857 million barrels, averaging 2.35 million barrels per day. Sulfur production increased to 640,000 tons, and cement showed a marked increase as new production units came onstream during the year.

Crude petroleum continued to be the nation's most important foreign exchange earner in 1977. Crude oil exports declined less than 1% in volume but increased 10.5% in value to $9.5 billion, representing 98% of the value of all exports. Sulfur exports were reported at 522,000 tons, with significant volumes destined for Egypt, the People's Republic of China, India, Tanzania, and Greece.[3]

COMMODITY REVIEW

METALS

Aluminum.—Completion of the 32,000-ton-per-year aluminum plant at An Nasiriya was rescheduled from 1977 to mid-1978, because shipments of equipment critical to the plant's operation had not yet been received. The plant was to have facilities for production of aluminum sheet, wire, foil, and household utensils. When completed, the plant was to provide employment for 800 persons.[4]

Iron and Steel.—Construction of the country's first steel mill by Creusot-Loire of France was in progress on the Khor al Zubair near Umm Qaşr in southern Iraq. Steel production at the 440,000-ton-per-year plant was to commence in early 1978 and would initially be based on domestic and imported scrap. The mill will have four 70-ton arc furnaces and ancillary facilities for preduction of rod, bar, sheet, and wire.

Creusot-Loire was also building two HyL direct-reduction modules at the mill site that were designed to produce 440,000 and 750,000 tons per year of sponge iron; the modules were scheduled to be completed by yearend 1978. In 1977, Iraq contracted Cia. Vale do Rio Doce of Brazil to supply 5.3 million tons of iron pellets over 5 years for the project. Auxiliary facilities to support the iron and steel mill included pumping stations and water pipelines to supply cooling and potable water from the Shatt al Arab, port facilities on the Khor al Zubair for materials receipt, and a 300 ton-per-day limestone quarry and crushing plant. Al-Bakr city was being built to provide housing and other amenities for the mill employees. The electricity generation capacity of the nearby Khor al Zubair powerplant was being doubled to 250 magawatts to ensure an adequate supply for the project.

NONMETALS

Cement.—In 1977, significant progress was made in achieving Iraq's goal of a 9-million-ton-per-year cement capacity by 1980. At Al-Kufa, about 170 kilometers south of Baghdad, the first kiln in a four-kiln kiln expansion program came on-line. Each kiln was to preduce 500,000 tons per year of ordinary portland cement. The $255 million expansion of the existing 225,000-ton-per-year plant was being done by F. L. Smidth & Co. A/S of Denmark and was

Digitized by Google

slated for completion in 1978. Cement production was based on the use of limestone and marl from the Al Khuraib deposits and clay from the Al-Raghala deposit. A 22.5-kilometer-long, 1-meter-wide belt belt conveyor system consisting of nine 2.5-kilometer-long segments was employed to transport crushed limestone from Al-Khuraib to Al-Kufa. Wet clay was transported 13 kilometers over public roads in 20-ton vehicles from Al-Raghala to the cement plant. At Badoosh, 20 kilometers north of Mosul, a 1,500-ton-per-day dry-process kiln was added, bringing capacity to 750,000 tons per year; a second 1,500-ton-per-day dry-process unit was under construction. At Al-Falluja, 60 kilometers west of Baghdad, a 400,000-ton-per-year wet-process kiln was added to the two existing 120,000-ton-per-year kilns, and a 100,000-ton-per-year white cement plant was nearing completion. At Hammam al' Alil, 20 kilometers south of Mosul, plant capacity was increased to 740,000 tons per year by the addition of a 1,500-ton-per-day wet-process kiln. Despite the increases in capacity, cement remained in short supply throughout the year.

Fertilizer Materials.—Nitrogen.—Mitsubishi Heavy Industries, Ltd., of Japan was constructing a new ammonia-urea complex on the Khor al-Zubair in 1977. Natural gas from the south Rumaila oilfield was to be utilized as feedstock for the complex, which was to consist of four units with a total nitrogen content capacity of 540,000 tons per year in ammonia and 486,000 tons per year in urea. The four units were to be commissioned in 1979 and were to triple the nation's existing output.[5]

Phosphorus.—Design and engineering work for the integrated Akashat phosphate rock mine/Al Qa'im fertilizer complex continued under the supervision of Syndicate Belge d'Entreprises a L'Etranger (Sybetra) of Belgium. Davy Powergas Ltd. of the United Kingdom was contracted to build the Al Qa'im fertilizer complex, which was to have sections for annual production of 1.5 million tons of sulfuric acid, 400,000 tons of phosphoric acid (P_2O_5), 600,000 tons of monoammonium phosphate, and 250,000 tons of complex nitrogen-phosphorus-potassium (NPK) fertilizers. Alusuisse Engineering was to provide units to produce 11,000 tons per year of aluminum fluoride and 6,400 tons per year of cryolite. F. L. Smidth received a contract in 1976 to build a beneficiation plant at the mine. Planned output from the Akashat mine was 3.4 million tons per year of phosphate rock averaging 21% P_2O_5. The annual production of 1.7 million tons of beneficiated product was to be shipped by truck over a new 230-kilometer road that was being constructed from the mine to Al Qa'im. The cost of the project was $940 million. Production was to be initiated in 1979 and reach full capacity in 1980.

Sulfur.—Iraqi sulfur production has remained fairly constantly well below design capacity because of the restriction placed on output by the inability of the transport system to provide the means of shipping the product from the producing areas in the north to the export terminals near the Persian Gulf. Most Iraqi production came from Misraq State Sulfur Co.'s operation located south of Mosul. A Polish modification of the Frasch process was used to extract sulfur from a bedded, cavernous deposit estimated to contain 200 million tons of sulfur. Sulfur was also produced from natural gas at the Kirkuk processing plant.

MINERAL FUELS

Natural Gas.—In 1977, Iraq continued to flare more than 80% of its associated natural gas production. Studies on utilization of natural gas from both northern and southern oilfields were underway during the year. A 200,000-ton-per-year propane-bottling facility was completed at Az Zubayr, and construction of a 35-kilometer-long, 122-centimeter-diameter natural gas pipeline from the south Rumaila oilfield to the Khor al Zubair was well along. Natural gas was to be utilized by the newly developing steel and fertilizer industries that were being built on the Khor al Zubair near Umm Qaşr.

Petroleum.—Crude petroleum production averaged 2.35 million barrels per day in 1977. Iraq continued to expand production capacity by drilling wells to further exploit the south Rumaila, Jabal Fauqi, and Bai Hassan oilfields. The drilling program at the Luhais field was designed to bring it on-line at 50,000 barrels per day in 1978. Expansion of the Basra oil refinery was underway in 1977 as Technoexport of Czechoslovakia began construction of a 70,000-barrel-per-day expansion to double the refinery's capacity. SNAM Progetti S.p.A. of Italy's Ente Nazionale Idrocarburi (ENI) group was to build a plant for production of 100,000 tons per year of lubricating oils and 200,000 tons per year of asphalt at

Digitized by Google

the Basra refining complex. Completion of the projects was to be realized in 1979.

The 1,005-kilometer Kirkuk-to-Dortyol (Turkey) crude oil pipeline was commissioned in 1977 at a rated capacity of 500,000 barrels per day. Turkey was to offtake 40% of its use; the remainder was destined for European markets. A petroleum products pipeline connecting the Basra and Durah refineries was also brought onstream during the year.

The Mineral Industry of Ireland

By William F. Keyes[1]

The Irish economy turned in a better performance in 1977 than any of its fellow members of the European Economic Community (EEC). There were sharp increases in investments, exports, and consumer demand, and the gross national product at constant prices rose 5%. Inflation, however, was still a problem, and the consumer price index was up 16.5% over that of 1976.

Except for lead and zinc, the mineral industry showed little change during the year, obtaining at best small increases in production. The major event was the coming onstream of the largest zinc mine in Western Europe. A new alumina plant was announced, plans were mooted to increase steel-melting capacity, and steady progress was made offshore in bringing Ireland's first natural gas field into production. On the other hand, a decision was announced just after yearend not to construct a zinc smelter to process domestic ores.

In 1977, about 50 companies held some 800 licenses to prospect over 40% of the surface of the country. These included such large U.S. and international companies as AMAX Inc., Rio Tinto-Zinc Corp. Ltd., New Jersey Zinc Co., Texasgulf Inc., Noranda Mines Ltd., ASARCO Incorporated, Johns Manville Corp., and Messina (Transvaal) Development Co. Ltd. Nevertheless, the last large ore body to be discovered in Ireland was the Navan zinc deposit in 1970, and some concern was expressed at the slow pace of discoveries to replace current mines when they are exhausted. Three mines (Silvermines, Tynagh, and Avoca) had very little reserves left.

The Irish Mineral Exploration Group (IMEG), representing 22 large companies such as Rio Tinto-Zinc, Tara Mines Ltd., and Noranda and holding over 80% of the exploration licenses, criticized the Irish Government's mining policies as discouraging prospecting. There was a change of government in 1977; in March, the former government had introduced new rules governing the terms of prospecting licenses, setting them at 2 years with extensions up to 6 years, and IMEG declared that 2 years was too short a term for the initial license. Nevertheless, the new Fianna Fail Government, although somewhat more oriented toward business, was not expected to alter the term.

PRODUCTION

Production of lead and zinc increased following startup of Tara's new Navan mine. Other mineral production was largely unchanged, and the outlook was uncertain in view of the unprofitability during 1977 of virtually all of the base metal mines.

[e]Estimate. [p]Preliminary. [r]Revised.

[1]In addition to the commodities listed, substantial quantities of stone and sand and gravel are produced by local authorities for such purposes as road maintenance, but data are not reported and available general information is inadequate to make reliable estimates of output levels.

[2]Excludes output by local authorities.

[3]Figures given as reported in source; includes output of granite, marble, silica rock, sand, calcspar, fire clay, and slate and clays for cement production, except that by local authorities.

[4]Includes output by farmers and by Bord Na Mona.

[5]Includes milled peat used in the production of peat briquets, listed elsewhere in this table.

TRADE

Ireland imports semimanufactured mineral products and exports concentrates of a number of base metals and nonmetallic minerals. Mineral trade with the United States consists principally of exports of barite, precipitated magnesia for refractories, and manufactured diamond, and imports of some lubricants, phosphate rock and potassic fertilizers, and iron and steel semimanufactures; trade with the United States is detailed in table 4.

COMMODITY REVIEW

METALS

Aluminum.—Late in the year, Alcan Aluminium Ltd. announced that it planned to proceed with construction of a $500 million alumina plant on Aughinish Island, County Limerick, in the Shannon estuary. Alcan had postponed the project early in 1976, when its partners in the project were A/S Ardal og Sunndal Verk of Norway and Gränges AB of Sweden. The renewed project was to be undertaken by Alcan (which took 40% ownership) in partnership with Billiton B.V. of the Netherlands (35%) and The Anaconda Company of New York (25%).

The plant, with a capacity of 800,000 tons per year of alumina, will have about 800 employees and will process imported bauxite. It was expected to be completed by 1982. Ireland was reportedly chosen as the site by Alcan because of its membership in the EEC, incentives offered by the Irish Government, and the availability of an excellent site well placed for shipping.

Copper.—Ireland's only copper mine, Avoca, was still unprofitable after 7 years of earnest effort by the present owner, Avoca Mines Ireland, a subsidiary of Avoca Mines Canada Ltd., in which the major shareholder (53.5%) is Discovery Mines Ltd. Messina (Transvaal) of the Republic of South Africa was interested in participating in the operation with further participation by the Irish Government, but it lost interest when copper prices declined to record low levels during the year.

A technical description of the mine was published.[2] Avoca is located in the Vale of Avoca, 40 miles south of Dublin, on the western bank of the Avoca River. The massive sulfide kuroko-type ore bodies, of Ordovician age, are associated with the Appalachian-Caledonian tectonic framework. The ore bodies are tabular, up to 60 feet wide and 1,500 feet long along the strike. Two underground lodes, the Pond and the South, are currently being worked, as is an open pit extension of the Pond ore. Mining underground is by blasthole stoping (45% of South lode mining) and by sublevel stoping (24% of Pond lode mining); the maximum mining depth is 900 feet but was formerly 1,200 feet. Access to the mine is by a decline to a depth of 1,400 feet, and the ore is brought to the surface on a conveyor belt. Mill-head grades average 0.64% copper and 7.16% sulfur. Two flotation concentrates are made: Copper (20% copper) and pyrite (48.5% sulfur). The copper concentrate is shipped through the port of Arklow to Spain and Sweden; the pyrite is bought by the Government fertilizer company Nitrigin Eireann Teoranta.

Iron and Steel.—Irish Steel Holdings Ltd. (ISH), the sole Irish steel producer, which is wholly owned by the Irish Government, announced plans to increase capacity at its scrap-processing plant on Haulbowline Island near Cork from 150,000 tons to 300,000 tons annually at a cost of about £40 million. It was hoped to get a loan of £20 million from the EEC.

The plan ran into opposition from the Commission of the EEC because of the surplus of steel capacity and plans for restructuring elsewhere in the EEC. There was also doubt that financing by the Irish Government would be permitted under EEC rules.

ISH suffered pretax losses of £1.25 million in the year ending June 30, 1977, and there was some question as to whether it could survive without modernization, which necessarily involved expansion of capacity. About 700 jobs were at stake.

Lead-Zinc.—Tara's Navan mine, a major addition to the world zinc industry, started up in June, almost 7 years after discovery of the deposit. Full rated output of 2.3 million tons per year of ore, equivalent to 400,000 tons of zinc concentrate (56% zinc) and 70,000 tons of lead concentrate (62% lead), will be attained late in 1978. Ore reserves, now estimated at 67 million tons of all classifications, were reported to contain 2.4% lead and 11.0% zinc. Several technical descriptions of the Navan mine were published.[3] The sphalerite-galena Navan ore body is a series of five superimposed tabular lenses in Lower Carboniferous limestone, aligned on a northwest-southeast axis and dipping 15° to 45° southwest, flattening out to 20° at depth. In the northeast, the lenses merge into a continuous vertical thickness of 60 meters. A major fault cuts the ore body along an east-northeast line, and the lenses on the southern side are downthrown about 75 meters. Depth to the ore body is 40 meters in the east and 200 meters at the shafts, some 350 meters down dip.

Digitized by Google

Access to Tara's ore body is through a three-compartment development shaft and a decline for mobile diesel equipment; there is also a 5-meter-diameter circular production shaft. Stoping is by an underground benching cut-and-fill method. Cemented mill tailings are used as mine fill. The concentration plant uses conventional flotation methods, which are effective, giving recoveries of 89% of the zinc and 71% of the lead. The concentrates were shipped in 1977 to nine European smelters through the port of Dublin.

The Bula lead-zinc property, adjacent to the Navan mine but north of the Blackwater River, a tributary of the Boyne River, was evaluated by an arbitration board at about £40 million. The Irish Government, in taking a 24% share, would therefore be obligated to pay about £9.75 million; the Government was also to receive another 25% without payment.

Work continued during the year on investigation of the other ore body in the Navan area, held by Sabina Industries of Canada, known as the Rennicks and Bennett property. Messina (Transvaal) was conducting the investigation jointly with Sabina.

The mine at Silvermines, controlled by Mogul of Ireland Ltd. (owned 75% by Kerr-Addison Mines Ltd. of Canada since 1976), was reported in the annual report of the holding company, Silvermines Ltd. of Dublin, to have reserves sufficient for about 5 years' operation at the present rate of extraction. During 1976, Mogul milled about 1 million tons with an average grade of 2.27% lead and 6.26% zinc, to produce 24,300 tons of lead concentrates and 94,440 tons of zinc concentrates. The only other lead-zinc mine presently operating in Ireland, the Tynagh mine of Northgate Exploration Ltd. of Canada, was reported to be operating at a loss because of low metal prices.

New Jersey Zinc, under contract with the Government, conducted a 6-month feasibility study for a proposed zinc smelter to initially produce 100,000 tons of zinc from Navan ore; this would be Ireland's first base metal smelter. Early in January 1978, the study was submitted to the Government; it concluded that low international prices, widespread capacity underutilization, and the unlikelihood of a rapid economic upswing made it advisable to postpone the projected completion date of the smelter from 1981-82 to 1984-85. At almost the same time, the Soviet Government approached the Irish Government with a proposal for cooperation in building the smelter. The Irish Government was studying this proposition.

Magnesium.—A second seawater magnesia plant was planned, this time at Drogheda, north of Dublin, where the old wet-process cement plant was to be converted to this use. Planned capacity of the plant was 100,000 tons per year of seawater magnesia. Approval from the Irish Government was awaited by Cement-Roadstone Holdings Ltd., which was prepared to spend up to £29 million on the project. The company was also seeking partners for the venture.

Current magnesia production in Ireland was by Quigley Magnesite, a subsidiary of Pfizer Inc. of the United States, from burned dolomite and seawater at Dungarvan on the southern coast.

NONMETALS

Cement.—Three cement plants were operated in Ireland during 1977 by Cement Ltd. of Dublin; total kiln capacity was 2,120,000 tons at yearend after one of these plants was closed. The largest plant, with 1.4 million tons of capacity, was the Platin plant near Drogheda, County Meath, which brought a new kiln into operation during the year; at about the same time, the old Drogheda plant nearby was shut down.

MINERAL FUELS

Energy.—Ireland produced peat, which was important in that it generated about one-fourth of domestic electricity, and a small amount of coal. There was no production of liquid or gaseous hydrocarbons, but an offshore gasfield was expected to come into production by 1979. The country's total primary energy balances for 1975 and 1976 are given in table 5.

Natural Gas.—Development work on the Kinsale Head gasfield of Marathon Petroleum Ireland Ltd. began in April with the placement of the first of two drilling-production platforms, each of which will contain one vertical and six deviated wells. The field, located 27 miles off the southeastern coast, is scheduled to come into production by April 1979 or earlier at a rate expected to reach 125 million cubic feet per day. The product will be sold to Bord Gais Eireann Teoranta (Irish Gas Board) and Nitrigin Eireann Teoranta.

Exports	.3	.1	.2	--
Apparent consumption	10.4	2.6	[2]7.7	.1

rRevised.
[1]1 ton standard coal equivalent (SCE)=7,000,000 kilocalories.
[2]Includes refinery fuel and losses.

Source: International Energy Agency, Organization for Economic Cooperation and Development (OECD). Energy Balances of OECD Countries, 1974/1976 (Paris). 1978.

Results of offshore drilling in 1977 were not very encouraging, and the Marathon gas strike continued to represent the only commercially exploitable hydrocarbon find. Wildcat holes were drilled by Ranger Oil (Canada) Ltd. and Cities Service Oil Co. off the southern coast. Shell-Agip and Deminex Ireland Ltd. (for Amoco and Mobil Oil Co. (Ireland) Ltd.) drilled in the Porcupine Bank off the western coast; both holes were plugged and abandoned. At yearend, Amoco continued drilling in the Kish Basin, 20 miles off the coast in Dublin Bay.

Uranium.—Aquitaine Mining Ireland, a subsidiary of the French Elf-Aquitaine group, engaged in an airborne spectrometer survey. The survey, conducted for Aquitaine by Hunting Geology and Geophysics Ltd., was completed in September, but results were not released.

The Mineral Industry of Israel

By David E. Morse[1]

The mineral industry of Israel, although small, is technologically advanced. Based on the recovery of dissolved solids from the Dead Sea and mining of phosphate rock, limestone, marble, various clay minerals, sand and gravel, and other dimension and crushed stone, the mineral industry furnished the foundation for Israel's cement, ceramic, construction, and nonmetallic chemical industries. Israel also had a flourishing refining and petrochemical industry based on imported crude oil. During 1977, mineral production increased because of the expanding world demand for fertilizer materials and the chemical products produced from Israel's minerals. Oil exploration remained active, and new discoveries were made in the Sinai.

The nation's economy continued to be sluggish in 1977. The gross national product (GNP) at $12.7 billion[2] was up only 0.5% in constant Israeli pounds over that of 1976. Inflation remained a major problem as the consumer price index escalated 34.6% during the year. While the economy stagnated, employment rose 4.4% to 1.2 million, and the unemployment rate remained below 4%. Israel has historically had a labor-deficient economy, and employers offered various incentives and concessions to keep skilled workers on the job.

On October 28, 1977, the Government decided to float the Israeli pound on the world market. Since July 1976, the pound had been pegged to a basket of five currencies and prior to that time to the U.S. dollar only. The float was accompanied by abolishment of the system of export premiums according to the value added and cancellation of the flat but not all-inclusive 15% levy on imports. The new policies effectively increased the cost of imports of goods and services nearly 25%.

PRODUCTION

Israel's mineral production increased significantly in 1977 because of the increased world demand for potash and phosphate rock. Beneficiated phosphate rock production nearly doubled to over 1.2 million tons, and potash sales increased by approximately 600,000 tons over the poor sales recorded in 1976. Output of elemental bromine, magnesite (periclase), and petroleum refinery products increased over that of 1976. Output of clay minerals, lime, and cement declined from the levels reported for 1976.

Table 1.—Israel: Production of mineral commodities

(Metric tons unless otherwise specified)

Commodity[1]	1975	1976	1977[p]
METALS			
Copper cement (70%-80% Cu):[e]			
Gross weight	10,000	--	--
Metal content	7,500	--	--
Iron and steel metal:[e]			
Pig iron	40,000	40,000	40,000
Crude steel	[r]57,000	[r]80,000	100,000
NONMETALS			
Bromine:			
Elemental	18,000	20,900	31,500
Compounds	12,000	10,300	20,350
Cement, hydraulic thousand tons	2,184	1,999	1,852
Clays:			
Flint clay	66,000	70,000	30,500
Metabentonite	3,000	15,000	8,000
Kaolin	12,000	10,000	5,500
Other	2,000	4,000	1,000
Fertilizer materials:			
Crude:			
Phosphatic:			
Unprocessed thousand tons	2,326	1,630	3,400
Beneficiated do	882	639	1,218
Potassic:			
Gross weight do	[r]1,140	1,115	1,159
K_2O equivalent do	[r]696	680	707
Manufactured:			
Nitrogenous	176,557	182,288	187,980
Phosphatic (superphosphate)	246,100	288,900	303,200
Potassic	8,742	9,509	9,876
Gypsum	200,000	200,000	200,000
Lime	240,000	200,000	102,000
Salt, marketed (mainly marine)	114,947	86,561	NA
Sand:			
Glass sand	74,000	84,000	83,500
Other (for building industry) thousand cubic meters	5,000	4,500	4,983
Sodium compounds, n.e.s.: Caustic soda	24,156	24,009	26,836
Stone:			
Dimension: Marble	16,000	16,000	22,000
Crushed thousand cubic meters	14,000	13,000	NA
Sulfur:			
Byproduct of petroleum	[r]10,000	10,000	10,000
Sulfuric acid thousand tons	194	208	198
MINERAL FUELS AND RELATED MATERIALS			
Gas, natural, marketed million cubic feet	2,105	2,055	2,010
Peat[e] thousand tons	20	20	20
Petroleum:			
Crude:			
From Israel proper thousand 42-gallon barrels	250	262	256
From occupied Sinai[2] do	27,095	6	--
Refinery products:			
Gasoline do	7,768	7,999	6,375
Kerosine do	1,994	1,893	5,619
Jet fuel do	4,334	4,521	--
Distillate fuel oil do	12,130	13,136	8,012
Residual fuel oil do	19,456	20,014	28,944
Lubricants do	201	262	--
Other do	3,984	3,371	2,838
Refinery fuel and losses do	2,077	2,133	2,158
Total do	51,944	53,329	53,946

[e]Estimate. [p]Preliminary. [r]Revised. NA Not available.

[1]In addition to the commodities listed, Israel reportedly has the capacity to produce 71 metric tons of U_3O_8 per year, but official data are not reported and available information is inadequate to make reliable estimates of output levels.

[2]Israeli control relinquished in November 1975.

TRADE

Israel's balance of trade remained highly unfavorable in 1977. Although exports increased 28% to approximately $3 billion, imports also rose over 16% which worsened the trade deficit by more than $4 million. The balance-of-payments picture brightened, however, as the deficit dropped from $3.3 billion in 1976 to $2.6 billion in 1977. Mining and quarrying exports were up 26% to $86.4 million because of increased exports of potash and phosphate rock. Mineral exports accounted for 3.3% of industrial ex-

Digitized by Google

ports which increased over 30% during 1977.

Polished diamond exports were up 41% over the 1976 value and exceeded $1 billion for the first time, although total carat sales increased only marginally over the 3.3 million carats sold in 1976. The cost of rough diamond imports increased more than 50% in 1977, which significantly decreased the diamond industry's profit margin.

Israel continued to rely heavily on imports for fuels and refined metals. The cost of imported fuels increased 10.6% and represented approximately 18% of the value of all imported materials.

Exports and imports of mineral commodities for 1975 and 1976 are shown in tables 2 and 3.

Table 2.—Israel: Exports of mineral commodities[1]

(Metric tons unless otherwise specified)

Commodity	1975	1976	Principal destinations, 1976
METALS			
Aluminum metal including alloys, all forms[2]	2,244	7,506	Switzerland 1,741; West Germany 1,254; Netherlands 951.
Copper:			
Copper cement	9,595	4,180	United Kingdom 3,395; Hungary 769.
Matte[3]	173	239	United Kingdom 104; Argentina 94; Hong Kong 35.
Metal including alloys:			
Scrap	[4]208	1,759	Belgium-Luxembourg 466; Italy 353; West Germany 314; Netherlands 191.
Unwrought and semimanufactures[5]	853	2,120	United States 1,149; Iran 453.
Iron and steel metal including alloys, all forms[6]	5,651	8,612	Iran 2,888; Romania 2,071; United States 1,025; West Germany 930.
Lead metal including alloys, all forms	53	589	West Germany 208; Belgium-Luxembourg 123; Malta 74; Republic of South Africa 62.
Nickel metal including alloys, all forms	2	34	United Kingdom 16; United States 8; Netherlands 4.
Other:			
Ash and residue containing nonferrous metals	407	562	Italy 231; West Germany 164; Netherlands 75.
Metals including alloys, all forms, value, thousands	$740	$375	Switzerland $86; Spain $82; Italy $42; Belgium-Luxembourg $41; Republic of South Africa $38.
NONMETALS			
Abrasives, natural, n.e.s.; Grinding and polishing wheels and stones, value	$198,000	$297,000	United States $136,000; Canada $82,000; West Germany $38,000.
Barite and witherite	411	163	Republic of South Africa 145; Finland 18.
Bromine[7]	1,367	2,010	United States 485; Argentina 361; Netherlands 221.
Clays and clay products (including all refractory brick):			
Crude[8]	1,081	779	Netherlands 705; Philippines 74.
Products:			
Refractory (including nonclay brick)	2,249	962	Greece 323; West Germany 244; Ethiopia 178; Iran 151.
Nonrefractory, value	$321,000	$272,000	Canada $198,000; Singapore $31,000; United States $26,000.
Diamond, gem, not set or strung[9], thousand carats	3,118	3,637	United States 1,213; Hong Kong 562; Netherlands 412; Belgium-Luxembourg 324.
Fertilizer materials:			
Crude, phosphatic	259,127	[10]341,445	Turkey 87,355; Italy 69,165; Belgium-Luxembourg 45,216; Romania 40,449.

COMMODITY REVIEW

METALS

Copper.—The Timna mining complex, located in southern Israel 20 kilometers north of Eilat, remained in care-and-maintenance status throughout 1977. Timna's remaining reserves were 14 million tons of oxide zone copper ore containing 1.1% to 1.3% copper when the operation was shut down at the end of March 1976.

NONMETALS

Bromine.—Dead Sea Bromine Ltd. increased output of elemental bromine over 50% to 31,500 tons in 1977. The company used the waste brines from the adjacent potash plant of its parent company, Dead Sea Works Ltd. (DSW), as the raw material for bromine production. Elemental bromine was produced by heating the brines in a chlorine atmosphere. Renovation and expansion work was underway during 1977 to bring plant capacity to 60,000 tons of bromine per year. Construction of a 100-ton-per-day chlorine gas plant at Sedom was virtually completed by yearend, and chlo-

Digitized by Google

rine production was to commence in early 1978. Chlorine gas had been obtained by transporting salt from DSW to Akko north of Haifa where chlorine was produced and then shipped back to Sedom. The chlorine plant was also to produce 112 tons per day of caustic soda, which was to be shipped to Arad for use at Dead Sea Periclase Ltd.'s (DSP) magnesium oxide plant.

Cement.—Nesher Israel Cement Enterprises Ltd., Israel's only producer, had an output of 1.85 million tons of ordinary portland cement during 1977. The company operated three plants. The 700,000-ton-per-year Haifa plant had four horizontal, rotary, wet-process kilns that were fired with fuel oil. The Bet Shemesh plant had a single dry-process, fuel oil-fired kiln with a capacity of over 600,000 tons per year. The Ramale plant had three rotary, wet-process, fuel oil-fired kilns with a capacity of 225,000 tons per year each. Israel's needs for white and other specialty cements were met by imports.

Fertilizer Materials.—*Phosphorus.*—For Negev Phosphates Ltd. (NPL), Israel's only producer of phosphate rock, 1977 was the company's biggest year in terms of crude and beneficiated rock output, although the sales value was below that of 1974. Phosphate rock production from the Oran and Little Crater mines returned to normal levels after the depressed years of 1975 and 1976. The Nahal Zin mine initiated production after March 31 and had an output of approximately 800,000 tons in 1977. The Nahal Zin operation was to produce 1 million tons of washed product grading 70% to 72% bone phosphate of lime (BPL) when full output is realized in 1980.

NPL produced 100,000 tons of phosphate rock from the Mishor Rotem mine for use in its phosphoric acid plant at Arad. The Arad plant utilized hydrochloric acid from the magnesium oxide plant of DSP to acidulate the 28% to 29% P_2O_5 material from the Mishor Rotem mine for phosphoric acid production. The plant produced 25,000 tons P_2O_5 in phosphoric acid in 1977.

During 1977, Israel Chemicals Ltd., NPL's parent organization, and West German partners established a joint venture company, Rotem Fertilizer Ltd. The company was to build a $30 million fertilizer complex based on the Mishor Rotem phosphate deposits. Initial plans called for construction of a 1,500-ton-per-day sulfuric acid plant and a 400-ton-per-day phosphoric acid plant to come onstream in 1981. Subsequently, phosphoric acid capacity would be doubled and facilities to produce super-triple-phosphate, ammonium phosphate, and complex fertilizers would be added.

Potassium.—DSW, located near Sedom at the southern terminus of the Dead Sea, operated at full capacity throughout 1977 although stocks on hand had risen to 700,000 tons of potash (KCl) at the end of March. Total sales during the year recovered from the low levels of 1976 and exceeded production, which allowed the company to reduce stocks considerably by yearend. DSW also produced industrial salts, table salt, and magnesium chloride salts that were used for medicinal purposes. The company's waste brines were utilized in the manufacture of elemental bromine and magnesium oxide. DSW planned to increase production capacity from 1.2 million tons to 1.5 million tons per year of potash by expanding the area of evaporation pans. Most of the output of DSW was destined for export.

Haifa Chemicals Ltd. produced high-purity potassium nitrate at its plants at Haifa. The company commissioned its second 110,000-ton-per-year plant in 1976, temporarily replacing the original plant of like capacity that had been damaged by a June 1976 fire. Repairs on the original plant were completed, bringing the company's capacity to 220,000 tons per year by yearend 1977.

Magnesium Compounds.—DSP, located near Arad in the north-central Negev Desert, distilled high-purity magnesium oxide from the waste brines of DSW's potash plant. The brines were pumped from Sedom on the southern shore of the Dead Sea to DSP's plant on the Rotem Plain. During 1977, production increased 11% to 27,800 tons. The company also produced approximately 60,000 tons of hydrochloric acid as a byproduct that was used by NPL in its nearby phosphoric acid plant. DSP planned to invest $8 million to expand capacity from 35,000 tons to 50,000 tons per year of magnesium oxide.

MINERAL FUELS

Energy.—The Ministry of Energy and Infrastructure was established in June 1977. The primary concerns of the new ministry were diversification of Israeli energy sources by utilizing coal and nuclear power, development of alternative energy sources, increasing oil exploration activities, expanding crude oil storage facilities, and increasing conservation. During 1977,

Digitized by Google

Israel was conducting energy research projects to develop the oil shale resources near Arad, the Huleh Valley lignite deposits, and solar energy systems. Preliminary studies were conducted to determine the feasibility of constructing a tunnel and hydroelectric complex to exploit the existing hydroelectrical potential between the Mediterranean and Dead Seas. Israel planned to build a nuclear powerplant to begin operation in the mid-1980's.

Coal.—The Government appropriated $400,000 during 1977 in an effort to find coal in the Negev Desert. A coalbed with thickness varying from 3 to 6 feet at a depth of over 300 meters near Dimona had been discovered while prospecting for oil. Preliminary studies indicated that the coal had a calorific value of 4,500 kilocalories per kilogram. A feasibility study was in progress during the year to reactivate the abandoned Jebel Maghara coal mine in the northern Sinai. Coal from the Jebel Maghara mine would be used to supply part of the coal requirements of the Hadera powerplant that was to have four 300-megawatt units and begin operation in 1980.

Petroleum.—Indigenous crude oil production from the Helez oilfield averaged less than 83 tons per day during 1977, only a fraction of the domestic requirement of nearly 19,500 tons per day. In 1977, oil in commercial quantities was found offshore near At-Tur in the southwestern Sinai, and a significant quantity of natural gas was discovered in the northern Sinai near Rafah.

Israel's two oil refineries, a 6.5-million-ton-per-year plant at Haifa and a 3.5-million-ton-per-year unit at Ashdod, were operated by Oil Refineries Ltd. Total refinery production was nearly 54 million barrels of product during the year, an increase of 1% over that of 1976.

The Mineral Industry of Italy

By Roman V. Sondermayer[1]

A domestic and international economic slowdown adversely affected the mining industry of Italy during 1977. Based on published indicators, the mineral industry showed a decline of about 5%. The sharpest individual decline was about 25% in production of nonferrous metals, mostly because of the closure of all mercury mines.

The Government-owned concern, Ente di Gestione per le Aziende Minerarie e Metallurgiche (EGAM) was abolished by a law passed by the Italian Parliament in 1977. EGAM had operated a number of Government-owned mineral facilities but showed large financial losses. Ente Nazionale Idrocarburi (ENI) took over the mines and associated metallurgical installations, and Istituto per la Ricostruzione Industriale (IRI) took over EGAM's iron and steel facilities. ENI and IRI, both also State-owned concerns, were to reorganize certain operations and close others, but at yearend no further information was available.

During 1977, major events in the mineral industry were as follows: Discoveries of lead and zinc were made; development of the Campiano (Grosseto) pyrite mine continued; discovery of the first titanium deposit in Italy was made public; a new rutile deposit was discovered in Liguria; several discoveries of hydrocarbons, mostly gas, were made; and the Malossa ultradeep oil and gasfield near Bergamo came onstream.

PRODUCTION

During 1977, output of minerals showed mixed results, as shown in table 1. The mineral industry and its processing sector were owned by both Government and private industry. Some unprofitable Government-owned companies were kept in operation to maintain employment.

Table 1.—Italy: Production of mineral commodities

(Metric tons unless otherwise specified)

Commodity		1975	1976	1977[p]

TRADE

Italy remained dependent on imports of many minerals and almost all mineral fuels. Details of foreign trade in 1975 and 1976 are shown in tables 2 and 3.

Table 2.—Italy: Exports of mineral commodities

(Metric tons unless otherwise specified)

Commodity	1975	1976	Principal destinations, 1976

NONMETALS —Continued			
Asbestos	81,073	82,833	West Germany 20,906; Japan 15,733; France 10,401.
Barite and witherite	16,079	24,344	Algeria 13,841; Libya 4,615; Egypt 3,473.
Boron materials:			
Crude natural borates	40	27	NA.
Oxide and acid	2,644	3,409	West Germany 1,340; France 877; Bulgaria 551.
Cement thousand tons	744	796	Libya 227; Israel 177; Algeria 102; Yugoslavia 91.
Chalk	779	750	NA.
Clays and clay products (including all refractory brick):			
Crude:			
Bentonite	19,061	23,478	West Germany 8,151; France 3,371.
Kaolin	40,917	51,001	France 39,927; Spain 6,100.
Other	7,350	1,273	United States 20.
Products:			
Refractory (including nonclay bricks)	84,998	80,497	West Germany 13,142; France 9,700; Romania 8,257; Algeria 6,492.
Nonrefractory thousand tons	1,041	1,669	France 391; West Germany 389; Austria 131, Switzerland 94.
Cryolite and chiolite	(1)	26	NA.
Diamond:			
Gem, not set or strung value, thousands	$7	$277	United Kingdom $178; Saudi Arabia $77.
Industrial do	$27	NA	
Diatomite and other infusorial earths	1,441	1,173	NA.
Feldspar	22,539	24,519	West Germany 10,556.
Fertilizer materials:			
Crude	6,610	6,470	France 4,908; Libya 418.
Manufactured:			
Nitrogenous thousand tons	720	1,115	Turkey 246; Egypt 174; El Salvador 129; India 105; People's Republic of China 103.
Phosphatic do	24	6	Libya 5; France 1.
Potassic do	68	94	Algeria 21; Greece 17; United States 10.
Other do	154	148	Zambia 54; France 28; West Germany 10.
Ammonia	63,332	40,860	Greece 37,792; Cameroon 1,289; Ivory Coast 1,000.
Fluorspar	84,416	104,609	United States 64,160; West Germany 31,711.
Graphite, natural	1,792	1,314	France 872.
Gypsum and plasters	10,559	9,653	France 1,261.
Lime	94,401	118,154	Libya 82,995; Switzerland 25,419.
Lithium ore	5	7	NA.
Magnesite	212	4,108	United States 2,100; United Kingdom 1,080.
Mica:			
Crude, including splittings and waste	499	1,084	West Germany 759.
Worked, including agglomerated splittings	65	104	NA.
Pigments, mineral including processed iron oxides	1,935	36,009	Austria 8,320; Turkey 7,259; Yugoslavia 4,609; France 4,429.
Precious and semiprecious stone except diamond:			
Natural value, thousands	$25	NA	
Manufactured kilograms	155	2,148	NA.
Pyrite (gross weight)	40,314	13,612	Switzerland 8,217; Austria 3,152; West Germany 1,683.
Salt, all forms	59,453	91,933	Denmark 28,380; Greece 14,630.
Sodium and potassium compounds:			
Caustic soda	300,240	357,826	Yugoslavia 94,844.
Caustic potash	869	1,591	NA.
Stone, sand and gravel:			
Dimension stone:			
Crude and partly worked:			
Calcareous	257,261	260,789	Spain 51,248; West Germany 29,547; France 26,050.
Slate	2,622	2,603	NA.
Other	76,352	98,395	West Germany 44,661; Switzerland 17,431.
Worked, all forms	697,355	867,622	West Germany 395,334; France 122,784; United States 73,076; Saudi Arabia 44,720.
Dolomite, all forms	22,437	24,169	Switzerland 4,412; Argentina 4,018; Austria 2,495.
Gravel and crushed rock	531,968	561,129	West Germany 127,193; Libya 101,337; Switzerland 92,708.
Limestone (except dimension)	67	90	NA.
Quartz and quartzite:			
Piezoelectric crystal kilograms	13,100	1,308	NA.
Other	41,576	37,393	Switzerland 15,568; France 12,538.
Sand excluding metal bearing	305,279	309,244	Switzerland 275,116.
Sulfur:			
Elemental, all forms	4,954	3,302	Yugoslavia 1,260; Cyprus 300.
Sulfur dioxide	96	407	NA.
Sulfuric acid	151,615	78,111	Turkey 46,075; Spain 8,555.

Table 2.—Italy: Exports of mineral commodities —Continued

(Metric tons unless otherwise specified)

Commodity	1975	1976	Principal destinations, 1976
NONMETALS —Continued			
Talc, steatite, soapstone	41,959	51,350	West Germany 16,343; United States 9,127; United Kingdom 8,074; France 5,607.
Other:			
Slag, dross and similar waste, not metal bearing	317,327	229,111	Yugoslavia 192,945.
Oxides, hydroxides, peroxides of magnesium, strontium, barium	1,962	9,417	Yugoslavia 4,100; Netherlands 3,116.
Building materials of asphalt, asbestos and fiber cement, and unfired nonmetals, n.e.s	105,929	149,872	France 53,078; Libya 37,541; West Germany 9,162; Morocco 4,869.
MINERAL FUELS AND RELATED MATERIALS			
Asphalt and bitumen, natural	1,692	1,937	Libya 1,670.
Carbon black and gas carbon	33,573	38,199	Austria 8,320; Turkey 7,259; France 4,679; Yugoslavia 4,609.
Coal, all grades, including briquets	4,253	5,226	Switzerland 3,594.
Coke and semicoke	796,979	825,883	Romania 402,203; Spain 141,275; Algeria 81,491.
Peat	267	637	NA.
Petroleum refinery products:			
Gasoline thousand 42-gallon barrels	31,654	36,414	United Kingdom 8,224; Netherlands 5,708; Switzerland 3,866; France 3,599.
Kerosine do.	16,159	16,841	Greece 2,299; Libya 1,514; United Kingdom 1,449; Netherlands 997.
Distillate fuel oil do.	45,848	34,294	France 4,155; Switzerland 4,111; West Germany 3,556; Netherlands 3,482.
Residual fuel oil do.	39,407	44,702	United States 11,928; Turkey 1,764; Libya 1,343; France 1,316.
Lubricants do.	3,251	2,527	Belgium-Luxembourg 416; West Germany 258; Netherlands 216; Switzerland 180.
Other:			
Liquefied petroleum gas do.	3,828	5,660	Turkey 1,447; Egypt 1,206; Spain 643; Greece 454.
Mineral jelly and wax do.	8	16	West Germany 10; Poland 2.
Bitumen and other residues do.	1,127	1,248	Austria 600; Switzerland 261; Tunisia 170.
Bituminous mixtures, n.e.s do.	79	85	Malta 24; Libya 18; Tunisia 18; Yugoslavia 12.
Petroleum coke and pitch coke do.	138	116	Greece 50; France 50; Yugoslavia 11.
Total	141,499	141,903	
Mineral tar and other coal-, petroleum-, or gas-derived crude chemicals	125,650	53,768	France 45,118; Spain 8,486.

[r]Revised. NA Not available.
[1]Less than 1/2 unit.

Table 3.—Italy: Imports of mineral commodities

(Metric tons unless otherwise specified)

Commodity	1975	1976	Principal sources, 1976
METALS			
Aluminum:			
Bauxite	1,829,887	1,823,630	Australia 1,383,677; Guinea 319,681.
Ash and residue containing aluminum	35,218	NA	
Oxide and hydroxide	66,427	110,722	Guinea 51,000; France 24,816; West Germany 11,377.
Metal including alloys:			
Scrap	33,465	43,500	West Germany 11,467; France 8,049; Austria 7,121; Netherlands 5,802; Switzerland 5,675.
Unwrought	130,904	225,503	West Germany 70,326; Greece 42,754; France 38,544.
Semimanufactures	36,555	52,228	West Germany 18,833; France 11,822.
Antimony:			
Ore and concentrate	728	1,090	Canada 499; Turkey 299; Bolivia 272.
Metal including alloys, all forms	184	229	Belgium-Luxembourg 75; United Kingdom 51.
Arsenic trioxide, pentoxide, acids	1,531	1,118	People's Republic of China 564; France 278.
Beryllium metal including alloys, all forms kilograms	3,400	1,800	NA.
Bismuth metal including alloys, all forms	159	103	France 77.
Cadmium	143	260	West Germany 201.

Table 3.—Italy: Imports of mineral commodities —Continued

(Metric tons unless otherwise specified)

Commodity	1975	1976	Principal sources, 1976
METALS —Continued			
Chromium:			
Chromite	160,728	234,912	Turkey 119,291; U.S.S.R. 35,020; Republic of South Africa 34,402; Albania 29,604.
Oxide and hydroxide	2,001	2,010	West Germany 1,309.
Metal including alloys, all forms	143	178	France 98; Netherlands 30; United Kingdom 30.
Cobalt:			
Oxide and hydroxide	314	295	Belgium-Luxembourg 238.
Metal including alloys, all forms	282	255	Belgium-Luxembourg 107; France 45.
Columbium and tantalum:			
Ore and concentrate	235	5	NA.
Metal, all forms, including waste and scrap	25	(1)	NA.
Copper:			
Ash and residue containing copper	277	485	NA.
Copper sulfate	1,944	1,949	Yugoslavia 1,088; France 612.
Metal including alloys:			
Scrap	55,940	68,089	France 18,825; West Germany 14,938; United States 11,778; United Kingdom 10,584.
Unwrought	299,179	315,065	Zambia 63,473; Chile 59,453; Belgium-Luxembourg 46,737.
Semimanufactures	26,483	45,783	West Germany 16,208; Belgium-Luxembourg 7,852; France 5,299; Greece 5,019.
Gallium, indium, and thallium kilograms	1,300	1,000	NA.
Germanium do	800	500	NA.
Iron and steel:			
Ore and concentrate thousand tons	15,650	17,055	Brazil 3,196; Liberia 2,880; Australia 2,548; Canada 2,098.
Roasted pyrite do	1	3	NA.
Metal:			
Scrap do	5,414	6,272	France 2,619; West Germany 2,070; United States 621; U.S.S.R. 342.
Pig iron including cast iron and spiegeleisen do	662	712	Brazil 191; West Germany 118; France 113; U.S.S.R. 71; Algeria 67.
Sponge iron, powder and shot do	15	37	Brazil 16; Sweden 9; France 6; West Germany 4.
Ferroalloys:			
Ferromanganese do	125	117	France 52; Norway 6; Spain 6; Portugal 6.
Other do	120	152	West Germany 43; France 30; Norway 21; Yugoslavia 14.
Steel, primary forms do	1,481	2,543	France 624; West Germany 265; Australia 265; Brazil 194.
Semimanufactures:			
Bars, rods, angles, shapes, sections do	468	728	France 203; Austria 79; Belgium-Luxembourg 67; West Germany 18.
Universals, plates, sheets do	1,054	1,504	France 555; Belgium-Luxembourg 211; West Germany 178; Austria 104.
Hoop and strip do	152	178	France 49; West Germany 36; Belgium-Luxembourg 21; Yugoslavia 10.
Rails and accessories do	77	66	West Germany 35; France 17; Netherlands 4.
Wire do	40	64	Belgium-Luxembourg 24; France 13; West Germany 12; Austria 5.
Tubes, pipes, fittings do	189	207	West Germany 72; France 58; Yugoslavia 23.
Castings and forgings, rough do	4	3	NA.
Total do	1,984	2,750	
Lead:			
Ore and concentrate	13,616	19,944	Poland 5,129; Greece 4,875; Canada 3,742.
Ash and residue containing lead	809	2,081	United States 1,493.
Oxide	3,391	3,678	France 1,317; Mexico 1,049.
Metal including alloys:			
Scrap	18,531	22,235	West Germany 5,909; France 5,672; United Kingdom 4,969.
Unwrought	129,511	157,345	West Germany 38,763; Australia 21,573; Mexico 18,028; Peru 14,943; Morocco 11,666.
Semimanufactures	640	977	NA.
Lithium	14	4	NA.
Magnesium metal including alloys:			
Scrap	795	1,643	West Germany 1,150; Netherlands 230.
Unwrought	230	141	Morocco 117; United Kingdom 10; West Germany 10.

Table 3.—Italy: Imports of mineral commodities —Continued

(Metric tons unless otherwise specified)

Commodity	1975	1976	Principal sources, 1976
METALS —Continued			
Magnesium metal including alloys —Continued			
Semimanufactures	145	195	United States 98.
Manganese:			
Ore and concentrate	315,382	355,919	Republic of Sourth Africa 186,038; Gabon 105,495.
Oxides	3,919	2,425	Belgium-Luxembourg 1,416; Japan 490.
Metal, all forms	1,921	1,756	Republic of South Africa 1,303; France 213.
Mercury 76-pound flasks	261	783	NA.
Molybdenum:			
Ore and concentrate	6,229	5,315	Netherlands 3,589; Belgium-Luxembourg 681.
Metal including alloys, all forms	92	262	Belgium-Luxembourg 120; Austria 52.
Nickel:			
Matte, speiss and similar materials	4,907	5,407	Canada 3,574; Cuba 943.
Metals including alloys:			
Scrap	833	1,450	Canada 698; Australia 147; Yugoslavia 145.
Unwrought	7,068	7,907	United Kingdom 2,411; Australia 731; United States 700.
Semimanufactures	2,324	2,251	West Germany 886; United Kingdom 561; United States 274.
Platinum-group metals and silver including alloys:			
Platinum group thousand troy ounces	434	364	West Germany 169; Republic of South Africa 56; United Kingdom 55.
Silver do	29,096	31,058	United States 10,320; United Kingdom 6,687; Belgium-Luxembourg 3,729.
Rare-earth metals:			
Oxides and other compounds value, thousands	$318	NA	
Metals:			
Cerium	4	10	NA.
Other	313	362	Austria 202; West Germany 143.
Selenium, elemental	25	33	Japan 13; West Germany 5.
Silicon, elemental	2,804	3,442	Republic of South Africa 1,431; France 1,357; Sweden 400.
Tellurium and arsenic	208	102	Sweden 63; United Kingdom 19.
Thorium value	$44	NA	
Tin:			
Oxide	35	13	NA.
Metal including alloys:			
Scrap	1	15	NA.
Unwrought	6,082	7,838	Malaysia 4,335; Indonesia 1,510.
Semimanufactures	138	171	NA.
Titanium:			
Ore and concentrate	102,929	161,272	Norway 138,080; Australia 23,059.
Oxides	26,049	39,026	West Germany 17,825; France 9,724.
Metal including alloys, all forms	r63	1,509	United States 739; U.S.S.R. 203; West Germany 151.
Tungsten:			
Ore and concentrate	240	108	Portugal 28; Republic of Korea 25; Austria 20; Mexico 20; United Kingdom 15.
Metal including alloys, all forms	63	91	France 27; West Germany 24.
Uranium metal	5	NA	
Vanadium oxide and hydroxide	527	397	Netherlands 185; Austria 175.
Zinc:			
Ore and concentrate	193,940	238,703	Canada 65,092; Peru 56,056; Greenland 28,357; Greece 25,849.
Ash and residue containing zinc	1,646	1,576	Switzerland 1,296.
Oxide and hydroxide	1,828	2,533	France 963; West Germany 589; Poland 320.
Metals including alloys:			
Scrap	2,971	2,565	West Germany 1,547; Belgium-Luxembourg 815.
Blue powder	1,752	53,569	Belgium-Luxembourg 13,689; West Germany 9,295; Zambia 7,821.
Semimanufactures	3,900	1,790	Belgium-Luxembourg 791; France 522; West Germany 403.
Zirconium:			
Ore and concentrate	34,530	44,440	Australia 43,229.
Metal including alloys, all forms kilograms	10,700	7,600	West Germany 4,600.
Other:			
Ore and concentrate	8,709	1,960	Australia 1,735.
Ash and residue containing nonferrous metals, n.e.s	4,146	4,952	France 378; Romania 208.
Oxides and hydroxides	4,404	6,790	Cuba 2,834; West Germany 1,466.
Metals including alloys, all forms:			
Metalloids	101	5	NA.
Alkali, alkaline earth and rare-earth metals, n.e.s	5,365	5,774	West Germany 4,237; France 1,468.

The United States had a negative mineral trade balance with Italy. Coal accounted for almost one-half of the value of imports from the United States, while residual fuel oil was the most valuable item exported to the United States. Table 4 gives details of mineral trade between the two countries in 1976.

COMMODITY REVIEW

METALS

Aluminum.—The aluminum sector of the Italian mineral industry operated on imported raw materials during 1977. Domestic output of bauxite, about 35,000 tons per year, supplied only slightly over 1% of total bauxite consumption. Although Italy produced about 260,000 tons each of primary aluminum and 225,000 tons of secondary aluminum, it was a net importer of aluminum.

No major events were registered in the aluminum sector. Six plants, with a total annual capacity of approximately 291,000 tons of primary aluminum, were in operation during 1977, of which the largest was the smelter at Porto Vesme, Sardinia. The following tabulation shows details on aluminum plants operating in Italy.

Company	Location	Annual 1977 capacity (thousand metric tons)
Alumetal S.p.A	Bolzano	50
Do	Fusina	36
Do	Mori (Trento)	20
Societa Alluminio Veneto per Azioni S.p.A.	Fusina	30
Do	Porto Marghera	30
Aluminio Sardo S.p.A	Porto Vesme, Sardinia.	125
Total		291

Iron and Steel.—Although the steel industry of Italy faced financial problems and the year 1977 was considered poor, steel companies were preparing to resume full-capacity production when the economic slowdown ended.

Italsider S.p.A. announced a decision to replace six open hearths with two 250-ton-per-year converters at the Oscar Sinigaglia Steelworks, Cornigliano (Genoa). Replacement should be completed by September 1979, and new steel capacity should reach 2.4 million tons per year. In addition, at the Cornigliano iron and steel works, Italsider committed several hundred million dollars to new and improved facilities, including a rebuilt blast furnace, a new continuous two-strand casting plant, and additions to the cold-rolling mill.

At Dalmine, Dalmine S.p.A. (of the Finsider Group) completed one 80-ton electric arc furnace, replacing an open hearth furnace. At the Piombino plant, also operated by Dalmine, construction continued on two new mills: A billet mill and a two-strand-wire rod mill.

Fiat S.p.A., one of Italy's major privately owned steel producers, regrouped its steelmaking activities under the name Teksid and started negotiating with the Government on a possible takeover of Breda Siderurgica S.p.A.'s and Soc. Nazionale Cogne's installations.

During 1977, as in the past, the steel industry of Italy was almost completely dependent on imported iron ore, and all of its requirements for coking coal had to be met through imports. The annual production capacity in 1977 was 17.1 million tons of pig iron and 34.8 million tons of steel. More than two-thirds of the steel capacity was in electric furnaces and Linz-Donawitz (basic oxygen) converters. Capacity utilization was about 67%. The major producer, the Government-owned Finsider Holding Group, produced 55% of Italy's steel output. During 1977, most major companies of the Finsider Group registered losses.

In the private sector, Acciaierie e Ferriere Lombarde Falck S.p.A., the second largest steel producer in Italy, distributed dividends.

Lead and Zinc.—Output of lead and zinc mines in Italy remained at about the same level during 1977 as in 1976. At the Montiponi mine, operated by Soc. Ricerca Gestione Ristrutturazione Miniere, Sarde (Sogersa), treating of old tailings started. The high water levels in workings interfered with production. At the Salafossa mine in northeastern Italy, operated by Soc. Mineraria e Metallurgica di Pertusola (Pertusola), exploration continued and discovery of a new ore body was announced. The new find is separated from the main deposit by a fault. Quality of ore was not reported, but reserves of about 1 million tons were implied.

Digitized by Google

The expansion of Pertusola's Crotone electrolytic zinc plant to 130,000 tons per year continued, and startup was scheduled for 1979 or 1980.

Zinc producers, particularly Pertusola, successfully concluded a legal battle against electric power suppliers who increased prices of electricity delivered to zinc electrolytic plants. The courts ordered a rollback of prices paid for this electricity.

In the Masua mine in Sardinia, operated by AMMI Sarda S.p.A., exploration continued. In addition, a new flotation plant with a capacity of 2,500 tons per day of ore came onstream.

Pyrite.—Operations at the new Campiano (Grosseto) mine, operated by Solmine S.p.A., were delayed by an influx of hot underground water, causing several months' delay until new pumps were installed. The largest producers of pyrite were the Niccioleta and Gavorrano mines, belonging to Solmine; both of these had to lower production during 1977 owing to a shortage of miners.

Titanium.—A deposit of titanium ore was discovered at Mount Beigna, near Varazze (Savona) by geological teams exploring for the companies holding the concession, the privately owned Soc. Metallurgica Italiana (SMI) and the State-owned Soc. Ricerca Mineraria (RIMIN). Reports indicated a large deposit with a metal content that would make operation of it economical. The ore body is located in a scenic area and attempts to start production would probably generate strong opposition.

At present, Italy imports about 200,000 tons of titanium ore per year from Norway, Australia, and Malaysia. A recent forecast set Italy's needs for titanium ore at 250,000 tons by 1980.

Rutile.—Exploration of the newly discovered Piampaludo rutile deposit in Liguria, owned by Mineraria Italiana S.p.A., could make Italy the first producer of rutile in Europe. At yearend 1977, proven reserves of hard-rock ore were reported at 150 million tons with an average rutile content of 3% to 5%. Another 400 million tons of ore was classified as resources. The project was in an early stage of development, with many unresolved problems, but a possible size for commercial operations was reported as 75,000 tons of rutile per year.

Italy has depended on imports of rutile to meet its demand, and production from the Piampaludo deposit could be useful.

Titanium ores were processed by Italsider at Lovere (Tassara di Berno), Italghisa Elettrosiderurgica di Bagnolo Mella, and Officine Elettrochimiche di Calusco d'Adda, all in northeastern Italy.

NONMETALS

Barite.—High unemployment and poverty in Calabria have led the Government to consider reopening the barite mine and plant near Catanzaro (Calabria), closed 4 years ago. In the past, barite facilities in Catanzaro were operated by Industrie Minerarie Meridionali S.p.A., and production ranged between 5,000 and 10,000 tons of white air-floated barite used in the paint industry. At yearend 1977, the decision to go ahead with the reopening had not been made. Reorganization of the Italian mining industry after EGAM's demise was mentioned as the main cause for the delay.

Italy produced barite from 18 mines; the largest producers were in the Province of Cagliari, in Sardinia. The country was a net exporter of barite, but the trend of production continued downward because of technical and financial difficulties and labor problems.

Clays—*Bentonite.*—Under pressure to close its unprofitable bentonite operations on the Island of Ponza, northwest of Naples, the Italian bentonite producer, S.A. Mineraria Isole Pontine (SAMIP), was actively exploring a number of other bentonite deposits in Italy. Most efforts went into exploration of deposits near Nuoro (Sardinia).

The principal bentonite deposits are located in Sicily and Sardinia, near Rome, and in Campobasso Province. Italy was a net importer of bentonite during 1976, the latest year for which complete data are available.

Cement.—The cement industry had an uneventful year. The number of plants in operation remained at 120. Total cement plant capacity was 72 million tons per year. Italcementi S.p.A. was the most important cement producer in the country, with about 37% of Italy's output. Italcementi's largest plants were located at Bergamo, Brescia, and Colleferro.

As in the past, Italy was a net exporter of cement in 1976, the latest year for which complete data are available. Raw materials for cement production were abundant in Italy.

Fertilizer Materials—*Potash.*—Potash was mined in Sicily, and exploration, with apparently positive results, was underway

Digitized by Google

near Milena, Vallone, and Realmonte, in the vicinity of Porto Empedocle. Industria Sali Potassici e Affinie (ISPEA), owned by the Federal and Sicilian Governments, remained the major company exploring for and producing potash in Italy.

Fluorspar.—During 1977, reduced output of fluorspar resulted from lower demand and keener competition from countries with lower labor costs and export incentives.

Fluorite was produced in Sardinia and in Lombardy, in the northern part of the Italian mainland. The largest Italian producers were Gruppo Aziendale Mineraria Silius S.p.A., operating in Sardinia, and Fluormine S.p.A., operating in northern Italy. Italy was self-sufficient in fluorspar, and imports and exports were of the same order of magnitude.

Olivine.—Cives Industria Estrativa of Savona, which operates an olivine mine and dry-processing plant at Vidracco near Valchiusella, about 50 kilometers north of Turin, was installing new dust extraction and air classification equipment. In addition, plans were prepared for a new warehouse and washing plant.

Until 1968, the bulk of Italy's olivine demand was met through imports. Austria and Norway were the principal suppliers. With development of the deposit at Vidracco and startup of the mine and dry plant, both now rated at 80,000 to 90,000 tons per year of foundry sand (on a single-shift basis), imports of olivine have been lowered substantially.

Salt.—Salt output remained static owing to lower demand by the depressed chemical industry, the principal consumer.

Salt was produced in four forms in Italy: Rock salt, salt in brine, solar salt, and vacuum salt. Rock salt, the major source of salt, was produced around Agrigento and Caltanissetta in Sicily, where 10 separate mines, operated by Soc. Salitaliana, had a capacity of 2 million tons of salt per year. Salt in brine was produced by Solvay & Cie. S.p.A. from solution mining of rock salt near Rosignano Marittimo in Tuscany. The State monopoly, Administrazione Autonoma dei Monopoli di Stato, produced salt in brine at Volterra, also near Rosignano Marittimo, but the brine was used for production of vacuum salt. Facilities for solar salt production were scattered around the country. Most was produced by the State monopoly, which owned the solar salt works at Margherita di Savoia on the Adriatic coast and two plants near Cagliari (Sardinia). Rumianca S.p.A. operated a third solar plant in the vicinity of Cagliari. The most important vacuum salt operation was the 900,000-ton-per-year plant at Ciro Marina in Calabria, operated by Societa Salitaliana. The Ciro Marina plant gets brine, through a 40 kilometer pipeline from a rock salt deposit at Timpa del Salto.

Sulfur.—No major events were reported in the sulfur sector of the Italian mining industry. The largest producer was the Pomezia open pit mine, south of Rome, operated by COMIRO. Although uneconomical, eight Sicilian underground mines remained in production to provide employment.

Other.—Asbestos was produced in the San Vittore open pit mine near Turin; feldspar deposits in production were located near Bergamo, Commo, Vercelli, and Trento; graphite was mined near Turin; and talc output was recorded in Valle d'Aosta, also near Turin.

MINERAL FUELS

Coal.—Except for lignite, there was virtually no production of coal in Italy during 1977. Imported coking coal met the demand of metallurgical installations.

Lignite was produced at two mines, Santa Barbara and Pietrafitta, both near Perugia, operated by Ente Nazionale Energia Elettrica (ENEL). All lignite output was used for fueling ENEL's thermal powerplants.

Imports	192.4	11.9	165.3	14.5	(2)	.7	--
Exports	29.6	.8	28.5	.1	(2)	.2	--
Apparent consumption	192.1	11.7	138.4	35.3	(2)	5.9	.4

[1]1 ton standard coal equivalent (SCE) = 7 million kilocalories.
[2]Less than 1/2 unit.

Petroleum and Natural Gas.—Exploration for hydrocarbons was intensive and rather successful; several discoveries, mostly gas, were made during 1977. However, new oil and gas derived from these discoveries will perhaps only slightly and temporarily improve the modest share of domestic production in Italy's energy supply.

Intensity of exploration was increased during 1977. A total of 71 wells, totaling about 230,000 meters depth, were drilled, roughly 28% more than in 1976. There were five offshore drilling rigs in operation, drilling mostly in the Adriatic Sea.

Agip Mineraria, with the well Settala I, discovered gas in shallow pay 18 kilometers east of Milan. During the test, the discovery well produced at a rate of about 500,000 cubic meters of gas per day from a depth of between 1,200 and 1,300 meters. In the Adriatic Sea, a consortium of Essence et Lubrificants de France (ELF), Azienda Generali Italiana Petroli S.p.A. (AGIP), ENI, the Montedison Group, and Petroprep of France announced an oil discovery in two exploratory wells in the Rospo Field, Italian exploration Zone B, near Tremiti Island. Reserves of crude oil (110° API gravity) were reported at 40 million tons. A production concession was represented, but production is not expected before 1980. Oil was discovered in the Nilde 2 well, located about 60 kilometers southwest of the town of Marsala at the southwestern tip of Sicily. However, further drillings and testings were necessary before the potential was known. In the Foggia area, an onshore test well drilled by Premiers Consolidated Oilfields Ltd., produced at a rate of about 100,000 cubic meters of gas per day.

During 1977, Zone F, the first offshore deepwater zone, was opened to exploration for oil and gas. Zone F, covering a total of 26,000 square kilometers offshore, extends along the coast from Reggio di Calabria in the Strait of Messina to a point approximately due east of Vieste in the Adriatic Sea. The State-owned ENI has already reserved 25% of Zone F for its own exploration, chiefly between Bari and the Strait of Otranto and from the town of Villapiana in the Gulf of Taranto to south of Siderno Marino in the Ionian Sea. There has been no drilling in Zone F; only seismic and other geological data have been gathered.

Production of oil and gas in Italy received an important boost from the start of regular production from the Malossa reservoir near Bergamo. The reservoir is one of the largest in Italy. The pay zone of highly fractured limestone is 800 meters thick and at the great depth of 5,600 to 6,400 meters. Bottom-hole pressures are rated at 15,000 pounds per square inch, and wellhead flow pressures are as high as 11,750 pounds per square inch. In addition, bottom-hole temperatures of 300° F and wellhead temperatures of 212° F have been recorded. Special high-pressure, high-temperature, noncorrosive wellhead equipment was installed at 11 producing wells in the Malossa area. During 1978, production of oil from this reservoir is expected to reach 1 million tons, with about 3.7 million cubic meters of gas per day. Peak output is projected at 2.5 to 3.0 million tons per year of crude and about 10 million cubic meters per day of gas. At this rate, the field will supply about 3% of domestic crude oil demand and 14% of domestic natural gas demand in 1979. The oil is 51° API gravity

Digitized by Google

with no sulfur content.

During 1977, 31 petroleum refineries were in operation with a total installed capacity of about 211 million tons per year. ENI and private Italian companies owned about 73% of the total capacity. Foreign-owned international companies owned the rest. The largest domestic Italian operator was the Attilio Monti Group, which owned 17% of total Italian refinery capacity; ENI followed with 14%. Exxon Corp., with 10% of total refinery capacity, was the largest foreign producer in Italy. The largest refinery was at Milazzo (Sicily) with a capacity of 25 million tons per year, operated by Mediterranea Raffineria Siciliana Petrol: S.p.A.

Uranium and Nuclear Power.—The Government-owned AGIP awarded a contract to Hunting Geology and Geophysics Ltd. to assist in the location of uranium deposits in northern Italy. Hunting was to carry out an airborne spectrometer program by two helicopters specially modified for airborne geophysics; this part of AGIP's survey was to be completed in fall 1978.

AGIP continued development of a uranium deposit with reserves estimated at 500 tons of U_3O_8, near Novara (Bergamo). The beginning of production was planned for 1979.

The Mineral Industry of Japan

By E. Chin[1]

In 1977, Japan's gross natural product (GNP) reached $692.8 billion in terms of current market prices.[2] In 1970 constant prices, the GNP increased from $336.2 billion in 1976 to $391.7 billion in 1977, a real growth of 5.5%. During 1960-73, the real growth of Japan's GNP averaged 8.1% annually. By 1974, Japan's economy suffered from excess industrial capacity as a result of decreased demand for its goods and merchandise in foreign markets following the world oil crisis in the fall of the previous year. In 1974, there was a negative growth rate of 1.3% for the economy; in 1975, Japan's industries began to rebound, posting a growth of 2.1%, and in 1976, real growth was 6.3%.

Throughout 1977, Japan's steel industry operated at about 70% production capacity. Output during the year was 102 million tons. Domestic demand for steel remained around 65.2 million tons, about the same level as in 1976. Private plant and equipment investments which accounted for nearly 50% of domestic demand for steel mill products, decreased from 20.5% of the GNP in 1973 to 15.1% in 1977. The slump in the shipbuilding industry, a major user, heavily reduced the demand for ship plates, further depressing the steel industry. To compensate for decreasing domestic demand, the industry sought to increase exports. There was a sizable increase in steel shipments to the People's Republic of China and other countries and especially to the United States. However, U.S. steelmakers voiced strong opposition to rising Japanese imports, and in December, the U.S. Government announced the decision to regulate imports of low-priced steel products.

In the nonferrous sector, Japan's aluminum smelters lost international competitiveness because of the high energy cost of imported fuels. Industry officials estimated that at a sales price of Y370,000 per ton of aluminum ingot, the smelter suffers a loss of Y20,000 to Y30,000 per ton. The Industrial Structure Council recommended to the Government drastic and stringent measures to rescue the ailing aluminum smelters (see "Aluminum"). The copper, lead, and zinc companies continued to face sluggish demand, price reductions, deteriorating profits, and swelling inventories. Banking institutions provided financing equivalent to Y30 billion for stockpile purchases until demand recovered. Meanwhile, Japanese participants in overseas mining ventures sought to curtail, postpone, or suspend operations until the world economic situation improved.

Japan relies on foreign fuels for 87.9% of its energy requirements. The supply of domestically produced energy was as follows, in percent: Hydroelectric power, 5.6; coal, 3.2; nuclear power, 2.1; and natural gas and domestic petroleum, 0.8. The bulk of the country's energy supply was imports of petroleum, coal, petroleum products, liquefied natural gas (LNG), liquefied petroelum gas (LPG), and natural gas, in that order.

In November 1975, the Cement Association of Japan formed an antirecession cartel to curb production as a means of coping with the prolonged decline in demand and, consequently, in price. By 1977, however, domestic sales were estimated to have returned to the relatively high level of around 69.5 million tons, compared with 76.7 million tons in 1973. To cover the slump in domestic sales, producers had pursued export sales which reached 6.5 million tons in 1977, an increase of 15% over those of 1976. The industry expects that the expanded national budget will help spur cement demand in public works projects in 1978.

In a survey by the Ministry of Construction at the end of March 1977, there were 428,363 registered construction companies, but the industry is dominated by 5 compa-

Digitized by Google

nies. Since 1973, there has been a sharp fall in private construction investments. Many of the companies turned to overseas markets to overcome poor domestic business conditions. The Overseas Construction Association of Japan, Inc., estimated that the number of foreign construction contracts awarded in 1977 rose 4.5% compared with that of 1976, to Y393,665 million. The Ministry of Construction, however, expected orders to decline, largely because of rising competitiveness from firms of the Republic of Korea.

Producers of chemicals and chemical fertilizers continued to be plagued by high energy costs, loss of international competitiveness, and the rising value of the yen. Industry and Government were developing plans to aid the industry through structural improvements, including plant scrapping. The chloralkali industry was encumbered by capital investments of Y240 billion in a switchover to diaphragm cells to prevent pollution. Japan is the world's largest fertilizer exporter but was facing stiff competition from newly established fertilizer plants in other countries and the unexpected yen appreciation.

Japan was one of the first nations to recover from the worldwide economic slump in the aftermath of the 1974 oil crisis. Its surpluses in trade and current accounts continued to rise annually from the low level in 1974 and dominate the country's overall balance of payments. Japan's favorable balance of trade had increased from $5.0 billion in 1975 to $9.9 billion in 1976, and then almost doubled to $17.3 billion in 1977. By yearend 1977, Japan's international oil reserves reached $22.8 billion compared with $16.6 billion at yearend 1976. Price movements accounted for a considerable part of the ballooning surplus. The yen quotation started the year at Y292.50=US$1.00; by February 9, the U.S. dollar equivalent reached Y285, then Y270 on April 12, Y260 on June 29, and Y263 on July 5; it stabilized between Y265 and Y266 from the latter part of July to the end of September, then reached Y260 on October 6, Y250 on October 28, and Y240 in December, subsequently hitting the year's high of Y238 and closing at Y240 at yearend.

Generally, the appreciation of the yen had two measurable effects on the domestic economy. According to an assessment by Japan's Economic Planning Agency (EPA), yen appreciation caused overall wholesale prices to decrease 18%. The study revealed that if the yen appreciated 10%, wholesale prices would drop by 3% and consumer prices 1% owing to the direct and indirect effects of the yen rise. Conversely, the yen appreciation distressed the export-oriented industries, causing cancellations of trade contracts. Many industries had been operating below capacity since 1974 and in 1977 were facing pressure owing to unemployment, unprofitability, and bankruptcy. As a result, many companies disposed of assets, such as land and stocks, and reduced or eliminated dividends.

Because of the prolonged business slump, corporations were weakened financially. Despite the dangers of mergers and corporate tie ups under depressed economic conditions, there were significant reorganizations in 1977. Osaka Iron & Steel Co., Ltd., and Ohtani Heavy Industry Co. formed a new company called Godo Steel Ltd. on June 1. Subsequently, Godo Steel Ltd., Nippon Satetsu Steel Co., and Koto Seiko Co. ratified an agreement to merge. C. Itoh & Co., Ltd., amalgamated with Ataka & Co. on October 1, becoming the nation's third largest general trader.

According to Teikoku Koshinsho and Tokyo Research, there were 18,471 business failures among firms with more than Y10 million liabilities, amounting to about Y2,980 billion in total liabilities. In March, Mie Shipyard filed under the Corporate Rehabilitation Law, becoming the first major shipbuilding company to fail. By far the largest bankruptcy in 1977 was Hashihama Shipbuilding Co. with liabilities running up to Y50 billion.[3]

Unemployment remained around 1 million, or about 2% of the work force, an unusual situation for Japan in which lifetime employment is an established practice. Surplus employment (the portion of employment which is not needed but is retained because of Japan's employment tradition) was estimated at several million. Slumping industries made employment adjustments in the form of personnel transfers to related firms. Mitsubishi Heavy Industries Ltd. transferred personnel to Mitsubishi Motor Corp. in 1976; and two transfers were made in 1977 in greater numbers. Sumitomo Metal Industries Ltd., and Kawasaki Steel Corp. also transferred personnel to the automotive sector during the year. Other corporations continued to be faced with a surplus of workers and were planning to cut back on

Digitized by Google

their work force during the next year.

Because of the protracted economic outlook domestically and abroad, Japanese corporations continued to be cautious with foreign investments. Investments in Europe leveled off and those in North America declined, and investments in Asia, Africa, the Middle East, and Latin America rose. Southeast Asia accounted for $1,245 million in investments; North America, $749 million; Latin America, $420 million; Europe, $337 million; and the Middle East, $278 million. Indonesia was the recipient of the largest share, $3 million, largely owing to a large LNG project, followed by the United States and Brazil. These three countries together accounted for about $1,862 million or about 53.8% of the year's overseas investments. Most of the foreign investments were in the manufacturing sector, including electrical machinery, chemicals, iron and steel, and nonferrous metals. The mining industry accounted for $995 million in foreign investments, an increase of 40.7% above the previous year.

Japan was the world's third largest plant exporter, after the United States and the Federal Republic of Germany. Exports of industrial plants, including fees for engineering services, were estimated to have reached $10 billion in 1977, compared with $8 billion in 1976. In late 1977, the Republic of Korea's Pohang Iron and Steel Co. (POSCO) awarded a Y100 billion order to several Japanese firms, including Y50 billion to the group of Mitsubishi Heavy Industries, Mitsubishi Electric Corp., Ishikawajima-Harima Heavy Industries Co. (IHI), Ube Industries Ltd., Chugai Ro Kogyo Kaisha Ltd., and Mitsubishi Corp. for a hot-rolling mill; Y20 billion to the IHI/Mitsui & Co., Ltd., group for a blast furnace; Y10 billion to the Kawasaki Heavy Industries Ltd./C. Itoh group for a convertor; and Y7 to Y8 billion to the group of IHI, Tokyo Shibaura Electric Co., Kurita Water Industries Ltd., and Toyo Menka Kaisha Ltd., for power generation plant and water treatment facilities. POSCO also contracted orders for port and harbor facilities with the Sumitomo Heavy Industries, Ltd., and the Marubeni Corp. group and for raw materials processing facilities with the group of Nippon Conveyor Co., Mitsui Miike Machinery Co., and Toyo Menka Kaisha. Other large industrial plant orders included a Y100-billion petrochemical plant for the German Democratic Republic placed with the Toyo Engineering Corp./Mitsui & Co. group; a Y95-billion cement plant for Saudi Arabia with the IHI/Nichinen Co. group; and a Y64-billion seawater desalination plant for Iran with the group of Mitsubishi Heavy Industries, Sasakura Engineering Co., and Sumitomo Shoji Kaisha Ltd.

The Japan Machinery Federation estimated that sales of ocean development equipment (particularly overseas sales of rigs and other oil drilling apparatus) reached Y328.2 billion in 1977, up 33.6% compared with the year before. Moreover, oil drilling rigs owned by Japan Drilling Co. and Japan Odeco S.A. were in full operation in waters near Japan and in offshore areas of the Middle East and Latin America. In other ocean-development-related projects, Sumitomo Shoji Kaisha and other Sumitomo-group enterprises joined International Nickel Co., Ltd. of Canada in experimental mining of manganese nodules off Hawaii in the fall. Additionally, the Ministry of International Trade & Industry (MITI) placed an order with a local shipbuilder in December for a special survey ship to search for manganese nodules. The ship, slated for completion in 1980, was scheduled to start exploration in the mid-1980's.

Scientific and technological research expenditures by the Government, academic community, and industrial firms totaled Y3,320.6 billion in 1977, up 11.6% from those of the previous year. Of the total, private corporations accounted for Y1,882.2 billion, of which about 92% was spent by industrial, electric, chemical, and transportation manufacturers. Research activities funded by colleges and universities totaled Y934 billion, and by the Government, Y504.4 billion. Research expenditures, by type of activity, included Y130 billion for nuclear energy development, Y118 billion for information processing, Y107.8 billion for environmental protection and pollution control, Y79.5 billion for aerospace development, and Y18.3 billion for ocean research and development.

The value of Japan's imported industrial technology, as measured by the annual value of compensation payments, is about 0.5% of the GNP. Currently, 57.7% of all industrial technological processes were developed domestically, compared with 4.8% completely imported technology. The remainder were either refined versions of imported processes or a combination of imported and domestic technology. In some respects, Japanese technology in steel pro-

Digitized by Google

duction, automobile manufacturing, and shipbuilding has surpassed that in many Western nations. Also, production technology for textiles, electrical machinery and appliances, and ceramics is considered very high by world standards. However, technology employed by Japan's producers of nonferrous metals, pulp and paper, and chemicals is considered generally below the levels of other industrialized nations.

PRODUCTION[4]

Japan is much more important as a consumer of raw materials and as a producer of intermediate and finished products than as an ore producer. Japan's production of clays, dolomite, limestone, and other aggregates for construction raw materials is only of minor significance. Domestic mine output of iron ore, copper, gold, silver, manganese, tin, lead, zinc, salt, and magnesia is supplemented by large imports to meet Japan's requirements in the production of value-added goods. Moreover, the aluminum industry is wholly dependent on imports of bauxite and alumina for metal production.

To meet the country's energy needs, virtually all forms of mineral fuels were imported to sustain Japan's industries. Domestic production of crude oil was less than 675,000 kiloliters, compared with imports of 265.0 million kiloliters. Imports of 1.5 million tons of anthracite coal compared with domestic production of 25,000 tons. Bituminous coal production was about 18 million tons; 59.6 million tons was imported mainly from the United States, Australia, and Canada.

In terms of mineral and metal processing, however, Japan's industries were very prominent, and output of refined metals and minerals products is large by world standards.[5] Japan ranked among the world's top three producers of iron and steel, aluminum, copper, zinc, cement, fertilizers, coke, and refined oil. It was also a major producer or the leading producer of lesser metals and minerals such as bismuth, cadmium, indium, selenium, silicon, tellurium, lime, seawater magnesia, talc, and pyrophyllite. In addition, Japan's output levels of lead, industrial gases (argon, nitrogen, and oxygen), and halogens (bromine and iodine) were among the top 10 in world production.

Production levels in mining and manufacturing in Japan recovered from the oil crisis of 1973, but industrial output has not regained the peak level of 1970-73. Indices of industrial production (1975=100) by major mineral-related sectors were as follows:

Sector	1973	1974	1975	1976	1977
Mining	112.8	105.8	100.0	100.0	103.1
Manufacturing	117.0	112.4	100.0	111.2	115.7
Iron and steel	118.8	116.9	100.0	109.5	108.1
Nonferrous metals and products	128.6	112.6	100.0	119.3	125.0
Fabricated metal products	133.4	123.0	100.0	116.8	124.9
Ceramic, stone, and clay products	126.5	117.0	100.0	110.4	115.2
Chemicals	110.2	109.9	100.0	111.5	117.2
Petroleum and coal products	106.6	104.4	100.0	102.7	104.7
Construction materials	130.5	115.5	100.0	109.6	110.0

In 1977, production of pig iron, crude steel, hot-rolled and cold-rolled ordinary steel products, and forged pieces was down from those of the previous year. There was a modest increase in output of hot-rolled specialty steel products, galvanized steel sheets, and iron castings. Production of electrolytic copper, rolled and extruded copper, and copper electric wire and cable increased compared with 1976 levels. The large increase in aluminum production was offset by growing industry stocks; cement output was up, and increased shipments resulted in lower inventory. Chemical fertilizer production was generally higher in 1977, as was production of soda ash and sulfuric acid; as opposed to output of fire brick, caustic soda, and titania decreased. Sales of petroleum refinery products were generally up during the year. Japan's overall supply of primary energy resources was up 5% in 1977.

[e]Estimate. [p]Preliminary. [r]Revised. NA Not available.

[1]Includes (but not limited to) ferromolybdenum, ferrotungsten, ferrovanadium, and silicochromium.

[2]Includes aplite, as follows, in thousand tons: 1975—324; 1976—358; and 1977—411.

[3]Data are for years ending June 30 of that stated.

[4]Includes byproduct sulfur from sulfide ores and the petroleum industry. Native sulfur is no longer produced.

[5]Includes a small amount of natural coke.

[6]Includes output from gas mines and coal mines.

TRADE[6]

Japan's total foreign trade in 1977 was $151,598 million, compared with $131,865 million in 1976. The value of exports increased 9% to $80,476 million in 1977, and imports decreased 1% to $71,122 million. The value of imports during the first 5 months of 1976 exceeded that of exports. In 1977, Japan had a negative trade balance in January and February, with the value of exports exceeding that of imports during the remainder of the year, resulting in a favorable trade surplus of $9,354 million for the entire year. Since 1970, Japan has had a trade deficit only in 1973-75, owing to the world oil crisis of 1973 and the ensuing worldwide recession.

Japan was a net importer of animal and vegetable products, hides, skins, apparel goods, wood, and paper products, jewelry, precious metals, and mineral products. Because of the country's advanced technology and strong industrial base, Japan was a net exporter of value-added goods. By value, the largest export category was vehicles, aircraft, vessels, and associated equipment, totaling $24,156 million. Exports of ferrous and nonferrous metals in various forms were valued at $14,175 million; exports of optical, audio, measuring devices, and precision instruments and apparatus, $5,792 million; exports of textiles, $4,606 million; and exports of chemicals, $3,453 million.

By region, shipments to the United States and Canada accounted for 27% of Japan's total exports, followed by Southeast Asia 21%, Western Europe 16%, the Middle East 11%, Latin America 8%, and Africa 6%. The United States continued to be the largest single market for Japanese products. Exports to the United States were valued at $19,674 million. The other principal export destinations were as follows, in million dollars: The Republic of Korea, 4,065; the Federal Republic of Germany, 2,779; Taiwan, 2,551; Liberia, 2,503; Australia, 2,338; Saudi Arabia, 2,331; Hong Kong, 2,317; the U.S.S.R., 1,956; the United Kingdom, 1,949; and China, 1,937.

Japan's receipts from the Middle East (mainly crude oil) accounted for 29% of the country's total imports; from the United States and Canada 22%, Southeast Asia 21%, Australia, New Zealand, and the Republic of South Africa 9%, and Western Europe 8%. The United States was the largest single supplier to Japan, exporting goods valued at $12,481 million. Other major exporters to Japan were as follows, in million dollars: Saudi Arabia, 8,538; Australia, 5,305; Indonesia, 5,020; Iran, 4,274; Canada, 2,900; Malaysia, 1,563; China, 1,546; and the Federal Republic of Germany, 1,501.

Mineral fuels continued to be the most important trade item for Japan, accounting for about 42% of the value of total imports in 1977. The value of the imported crude oil alone during the year was $22,579 million and was principally from Saudi Arabia ($6,996 million), Iran ($3,970 million), and the United Arab Emirates ($2,707 million). Imports of steam coal totaled 1,489,110 tons

Digitized by Google

valued at $74.2 million. Major suppliers were Vietnam, China, the Republic of South Africa, North Korea, and the U.S.S.R., in that order.

The principal mineral imports in 1977 included bauxite, copper ore and concentrates, iron ore and concentrate, lead and zinc ores and concentrates, and nickel ore. Other large-volume import items were abrasives, caustic soda, clays, fertilizers, pyrite, and salt.

Table 2.—Japan: Exports of mineral commodities[1]

METALS				
Aluminum:				
Bauxite and concentrate ---------- tons	860	1,066	660	Republic of Korea 800; Taiwan 200.
Oxide (alumina) and hydroxide ----------	57	123	203	Republic of Korea 36; U.S.S.R. 28; Taiwan 22.
Fused alumina ---------- tons	5,290	8,820	11,175	Republic of Korea 4,160; Taiwan 3,730.
Metal including alloy, all forms ----------	r135	137	193	Republic of Korea 33; United States 21; Taiwan 8.
Arsenic trioxide, pentoxide, acids ------ tons	6	5	12	Taiwan 3; Indonesia 2.
Beryllium metal including alloys, all forms kilograms	91	188	223	Republic of Korea 98; Romania 80.
Bismuth metal including alloys, all forms -tons	362	306	302	Netherlands 127; United States 126.
Cadmium metal including alloys, all forms do	1,471	1,841	784	East Germany 606; Netherlands 580.
Chromium:				
Chromite ---------- do	364	2,089	2,805	Republic of Korea 1,074; Australia 1,002.
Oxide and hydroxide ---------- do	749	1,102	2,033	United States 444; Republic of Korea 303.
Cobalt oxide and hydroxide ---------- do	12	11	10	Republic of Korea 6; Taiwan 4.
Columbium and tantalum: Tantalum metal including alloys, all forms ---------- kilograms	8,971	14,934	45,469	West Germany 10,400; United States 4,292.
Copper:				
Ore and concentrate ---------- tons	4,799	--	--	
Copper sulfate ---------- do	r1,523	331	560	Taiwan 134; Thailand 61; West Germany 60.
Metal including alloys, all forms ----------	117	163	224	United States 37; Hong Kong 21; Republic of Korea 19.
Iron and steel:				
Ore and concentrate ---------- tons	--	5	12	All to Taiwan.
Metal:				
Scrap ---------- do	274,759	202,659	210,740	Republic of Korea 148,721; Thailand 36,394.
Pig iron, including cast iron ---- do	406,846	2146,331	2563,911	United Kingdom 57,163; Italy 43,200.
Sponge iron, powder, shot ---- do	7,995	9,739	10,602	Australia 2,193; Taiwan 1,923.
Ferroalloys:				
Ferromanganese ----------	131	122	49	United States 91; Netherlands 14.
Other ----------	129	89	27	United States 43; Netherlands 24.
Steel, primary forms ----------	6,360	5,669	4,659	Republic of Korea 836; Spain 782; United States 716.
Semimanufactures:				
Bars, rods, angles, shapes, sections --	r6,222	9,389	7,571	United States 1,796; People's Republic of China 899.
Universals, plates, sheets:				
Universals, plates, sheets, uncoated ----------	8,212	10,976	10,999	United States 1,702; People's Republic of China 1,562.
Tinned plates and sheets ----	865	785	908	United States 208; U.S.S.R. 76; Singapore 42.
Other coated plates and sheets --	1,465	r2,440	2,580	United States 1,114; Iran 162.
Hoop and strip ----------	563	967	1,006	Republic of Korea 35; U.S.S.R. 33.
Rails and accessories ----------	240	156	218	Brazil 36; United States 30.
Wire ----------	382	419	456	United States 160; Hong Kong 18.
Tubes, pipes, fittings ----------	4,541	5,192	5,206	U.S.S.R. 1,481; United States 1,090.
Castings and forgings, rough ------	15	28	30	United States 16; Canada 2.
Lead:				
Ore and concentrate ---------- tons	--	3,728	6,964	All to North Korea.

Table 2.—Japan: Exports of mineral commodities[1] —Continued

(Thousand metric tons unless otherwise specified)

Commodity	1975	1976	1977	Principal destinations, 1976
METALS —Continued				
Lead —Continued				
Oxide ____ tons	266	965	382	Vietnam 700; Taiwan 120.
Metal including alloys, all forms	42	r13	12	Republic of Korea 5; Taiwan 2; U.S.S.R. 2.
Magnesium metal including alloys, all forms ____ tons	r1,791	1,128	405	Netherlands 350; Australia 305.
Manganese:				
Ore and concentrate ____ do	3,976	6,128	5,206	Taiwan 1,280; Republic of Korea 1,132.
Oxide	23	34	24	United Kingdom 3; United States 3.
Mercury ____ 76-pound flasks	1,923	1,223	2,299	Republic of Korea 681; Netherlands 200.
Molybdenum metal including alloys, all forms ____ tons	16	18	43	Hungary 11; Republic of Korea 5.
Nickel:				
Ore and concentrate ____ do	r4	15	30	All to Sweden.
Metal including alloys, all forms ____ do	3,378	5,523	6,083	Netherlands 795; United States 621.
Phosphorus, elemental (red) ____ do	182	r186	98	United States 51; India 45; Taiwan 35.
Platinum-group metals and silver:				
Waste and sweepings ____ do	1	(3)	5	NA.
Metals including alloys:				
Platinum group thousand troy ounces	168	115	124	Taiwan 86; Hong Kong 9.
Silver ____ do	8,548	3,691	2,343	United States 2,126; Republic of Korea 485.
Selenium, elemental ____ tons	318	352	296	Netherlands 221; United States 51.
Tin:				
Oxide ____ do	17	29	3	Hong Kong 10; North Korea 8; Republic of Korea 6.
Metal including alloys, all forms ____ do	794	r707	941	Republic of Korea 215; Indonesia 97.
Titanium:				
Oxide	34	37	18	United States 23; United Kingdom 6.
Metal including alloys, all forms ____ tons	3,274	1,680	2,312	United States 1,258; Netherlands 140.
Tungsten metal including alloys, all forms ____ do	200	184	130	United States 50; Singapore 45; U.S.S.R. 33.
Zinc:				
Oxide ____ do	3,688	2,591	1,761	Taiwan 964; Vietnam 530; Cuba 328.
Metal including alloys, all forms	59	82	77	Republic of Korea 10; U.S.S.R. 10.
Other:				
Ores and concentrates:				
Of titanium, molybdenum, tantalum, vanadium, zirconium ____ tons	4,470	1,346	678	Taiwan 295; Republic of Korea 209; Spain 209.
Of base metals, n.e.s ____ do	--	(4)	5	NA.
Ash and residue containing nonferrous metals ____ tons	3,769	7,188	6,279	United States 2,604; Belgium-Luxembourg 1,326.
Oxides, hydroxides, peroxides of metals ____ do	2,067	1,373	1,361	United States 471; Republic of Korea 242.
Metals including alloys, all forms:				
Phosphorus and other metalloids ____ do	806	465	246	Taiwan 284; Republic of Korea 124.
Alkali, alkaline earth, rare earth metals ____ do	186	188	292	Taiwan 178; Republic of Korea 6.
Pyrophoric alloys ____ do	80	74	76	France 22; United States 13; Nepal 11.
Base metals including alloys, all forms, n.e.s ____ do	5,027	r6,406	5,982	United States 1,903; Netherlands 846.
NONMETALS				
Abrasives, natural, n.e.s.:				
Emery ____ do	701	919	1,134	Taiwan 597; Republic of Korea 235.
Natural abrasives, n.e.s ____ do	160	275	147	Taiwan 186; Brazil 60.

See footnotes at end of table.

Table 2.—Japan: Exports of mineral commodities[1] —Continued

(Thousand metric tons unless otherwise specified)

Commodity	1975	1976	1977	Principal destinations, 1976
NONMETALS —Continued				
Abrasives, natural, n.e.s. —Continued				
Dust and powder of precious and semiprecious stones ____ thousand carats	769	33,339	1,111	West Germany 32,500; United States 734.
Grinding and polishing wheels and stones ____ tons	3,090	4,224	4,721	United States 599; Thailand 426.
Asbestos ____ do	2,158	3,529	1,226	Republic of Korea 2,334; Taiwan 1,134.
Barite and witherite ____ do	95	--	1,250	
Boron materials:				
Crude natural borates ____ do	507	60	17	All to Taiwan.
Oxide and acid ____ do	343	363	382	Vietnam 200; North Korea 60.
Cement ____	4,098	5,850	6,683	Kuwait 1,197; Singapore 1,119.
Chalk ____ tons	--	50	17	Philippines 30; Taiwan 17; United States 3.
Clays and clay products (including all refractory brick):				
Crude ____ do	30,455	37,433	53,360	Taiwan 18,703; Republic of Korea 6,225.
Products:				
Refractory ____ do	125,725	118,369	165,203	Republic of Korea 21,571; Brazil 10,613.
Nonrefractory[5] ____ do	52,445	44,571	55,410	United States 10,977; Australia 9,947.
Cryolite and chiolite ____ do	20	10	2	All to New Zealand.
Diamond:				
Gem, not set or strung ____ carats	3,200	1,664	798	Mainly to Hong Kong.
Industrial ____ thousand carats	4	(6)	1	Mainly to Republic of Korea.
Diatomite and other infusorial earth ____ tons	908	1,151	1,024	Taiwan 467; Australia 208; Poland 195.
Feldspar and fluorspar:				
Feldspar ____ do	4,495	9,512	11,224	Mainly to Taiwan.
Fluorspar, leucite, nepheline, nepheline syenite ____ do	343	1,050	840	New Zealand 505; Vietnam 400.
Fertilizer materials:				
Manufactured:				
Nitrogenous[7] ____	2,734	1,874	2,478	People's Republic of China 692; Brazil 215; Taiwan 122.
Phosphatic ____	9	18	23	Taiwan 9; Fiji 6.
Potassic ____	6	5	2	Indonesia 2; Philippines 2.
Other, including mixed ____	r125	80	43	Thailand 54; India 11.
Ammonia ____ tons	279,702	284,996	242,768	Philippines 259,817; Netherlands 7,873.
Graphite, natural ____ do	860	1,704	1,311	Taiwan 913; United States 450; Iran 122.
Gypsum and plasters ____ do	2,584	15,712	6,474	Taiwan 6,247; Indonesia 5,190.
Iodine ____ do	5,116	(8)	(8)	
Kyanite and related materials ____ do	8,592	10,165	16,496	Taiwan 7,725; Thailand 1,211.
Lime ____ do	31,364	34,312	29,287	Papua New Guinea 15,448; Kuwait 8,400.
Magnesite ____ do	324	405	5,299	Taiwan 150; Republic of Korea 140.
Mica ____ do	209	349	411	Hong Kong 132; Taiwan 122.
Pigments, mineral: Iron oxides, processed ____ do	5,746	12,141	12,554	United States 6,192; Taiwan 2,380.
Precious and semiprecious stones, except diamond:				
Natural ____ kilograms	84,207	240,899	135,208	Taiwan 143,725; Republic of Korea 50,131.
Manufactured ____ do	21,521	32,184	26,826	Republic of Korea 14,882; Netherlands 5,248.
Salt and brines ____ tons	1,858	1,059	958	Papua New Guinea 408; Republic of Korea 294.
Sodium and potassium compounds, n.e.s.:				
Caustic soda ____	365	211	164	Australia 185; Republic of Korea 14.
Caustic potash and sodic and potassic peroxides ____	5	5	5	Australia 2; Taiwan 1.
Stone, sand and gravel:				
Dimension stone ____ tons	330	1,095	332	Taiwan 337; Egypt 219.
Dolomite, chiefly refractory grade ____ do	7,284	6,909	6,340	Philippines 6,220; Taiwan 589.
Gravel and crushed rock ____ do	1,348	9,712	6,936	Australia 8,000; Taiwan 873.
Limestone (except dimension) ____	1,439	1,488	1,212	Mainly to Australia.
Quartz and quartzite ____ tons	219	133	478	Thailand 98; Taiwan 31.
Sand excluding metal bearing ____ do	1,134	1,899	1,813	Taiwan 824; Republic of Korea 339.

Table 2.—Japan: Exports of mineral commodities[1] —Continued

(Thousand metric tons unless otherwise specified)

Commodity	1975	1976	1977	Principal destinations, 1976
NONMETALS —Continued				
Sulfur:				
Elemental:				
Other than colloidal ---------tons--	117,267	335,660	467,929	Republic of Korea 232,117; Taiwan 64,482.
Colloidal ---------do----	831	457	519	Republic of Korea 248; Taiwan 163.
Sulfur dioxide ---------do----	108	55	20	Australia 33; Republic of Korea 13.
Sulfuric acid ----------	r60	r117	290	Philippines 57; Turkey 17; Spain 16.
Talc and steatite ---------tons--	454	1,499	1,721	Vietnam 500; Taiwan 253; Bangladesh 183.
Other:				
Crude ----------	7	10	9	Indonesia 5; Taiwan 2.
Slag, dross, and similar waste, not metal bearing ----------	37	r67	218	Republic of Korea 32; Singapore 17.
Oxides, hydroxides, and peroxides of magnesium, strontium, and barium (including clinker) ----------	168	125	145	Poland 18; Australia 13; France 12.
Fluorine and bromine ---------tons--	(6)	r 8 5,517	8 5,484	United States 2,775; United Kingdom 566.
MINERAL FUELS AND RELATED MATERIALS				
Asphalt and bitumen, natural ---------do----	--	--	9	
Carbon black and gas carbon:				
Carbon black ----------	21	23	23	Taiwan 6; Thailand 5; Indonesia 2.
Gas carbon ---------tons--	--	r16	--	Singapore 9; Taiwan 7.
Coal, all grades, including briquets ----------	26	51	32	Republic of Korea 37; Taiwan 11.
Coke and semicoke ----------	733	540	530	Peru 126; Venezuela 95.
Gas, manufactured only ---------tons--	2	(9)	(9)	
Hydrogen and rare gases (helium, neon, krypton, xenon) ---------do----	r425	449	799	Iran 96; Republic of Korea 70; Taiwan 69.
Petroleum:				
Crude and partly refined thousand 42-gallon barrels--	4	(6)	(6)	All to United States.
Refinery products, nonbunker:				
Gasoline ---------do----	12	--	--	
Kerosine and jet fuel ---------do----	66	11	7	Mainly to Netherlands.
Distillate fuel oil ---------do----	47	129	5	Thailand 115; Republic of Korea 13.
Residual fuel oil ---------do----	8,415	3	72	Indonesia 2; Taiwan 1.
Lubricants ---------do----	r1,831	r1,273	2,066	Republic of Korea 528; Taiwan 190.
Other:				
Liquefied petroleum gas ---do----	92	54	40	Vietnam 31; Hong Kong 21.
Naphtha ---------do----	677	(6)	28	NA.
Mineral jelly and wax ---------do----	237	199	447	Republic of South Africa 35; Republic of Korea 31.
Bitumen ---------do----	136	184	39	Burma 119; Vietnam 55.
Unspecified ---------do----	r153	r117	170	Italy 40; Republic of Korea 35.
Mineral tar and other coal-, petroleum-, or gas-derived crude chemicals ----------	r71	95	77	Republic of Korea 45; Taiwan 16.

rRevised. NA Not available.

[1]Excludes exports under the Japanese-United States Mutual Defense Agreement or for account of the U.S. military forces.

[2]Includes spiegeleisen, if any.

[3]Value only reported at $41,460.

[4]Value only reported at $24,124.

[5]Excludes mosaic tile valued as follows: 1975 - $53,628,026; 1976 - $71,600,536; 1977 - $82,726,943.

[6]Less than 1/2 unit.

[7]Includes exports of the following amounts of urea containing more than 45% N: 2,205,265 tons in 1975; 746,453 tons in 1976; and 1,047,585 tons in 1977.

[8]Iodine is inseparable from fluorine and bromine.

[9]Same as gas carbon.

Table 3.—Japan: Imports of mineral commodities[1]

(Thousand metric tons unless otherwise specified)

Commodity	1975	1976	1977	Principal sources, 1976
METALS				
Aluminum:				
Bauxite and concentrate	4,600	4,277	5,318	Australia 2,717; Indonesia 967.
Oxide and hydroxide	561	r627	933	Mainly from Australia.
Fused aluminum (artificial corundum) tons	598	1,292	3,942	India 901; West Germany 166.
Metal including alloys:				
Scrap	29	69	70	United States 47; Canada 8.
Unwrought	378	430	534	New Zealand 105; U.S.S.R. 69; Bahrain 63.
Semimanufactures	22	21	23	United States 6; Romania 5.
Antimony:				
Ore and concentrate tons	9,012	12,703	7,501	Bolivia 8,444; People's Republic of China 819.
Metal including alloys, all forms do	r454	1,055	1,239	People's Republic of China 811; Bolivia 146.
Arsenic:				
Natural sulfides do	20	--	4	
Trioxide, pentoxide, acids do	906	r1,360	1,076	People's Republic of China 767; France 396.
Beryllium metal including alloys, all forms kilograms	1,922	3,835	6,098	All from United States.
Bismuth metal including alloys, all forms tons	(2)	--	--	
Cadmium metal including alloys, all forms kilograms	1	--	--	
Chromium:				
Ore and concentrate	1,269	1,217	900	Republic of South Africa 416; India 238.
Oxide and hydroxide tons	1,088	2,579	3,061	West Germany 904; United States 827.
Cobalt:				
Oxide and hydroxide do	252	754	597	Belgium-Luxembourg 689; United States 26.
Metal including alloys, all forms do	r1,582	3,931	2,083	Zaire 2,658; Zambia 482.
Columbium and tantalum:				
Columbium (niobium) ore and concentrate do	2,350	1,813	1,751	Brazil 611; Nigeria 484.
Tantalum:				
Ore and concentrate do	62	62	170	Mainly from Australia.
Metal including alloys, all forms do	21	50	47	Mainly from United States.
Copper:				
Ore and concentrate	2,605	2,587	2,823	Philippines 814; Canada 742.
Copper sulfate[3] tons	r243	155	376	Mainly from People's Republic of China.
Metal including alloys:				
Scrap	39	34	41	United States 16; Taiwan 7.
Unwrought	184	233	272	Zambia 113; Chile 43; Canada 15.
Semimanufactures tons	1,729	r1,455	r1,239	United States 864; West Germany 181.
Germanium:				
Dioxide do	4	9	8	U.S.S.R. 6; West Germany 2.
Metal including alloys, all forms kilograms	5	16	826	Italy 10; Belgium-Luxembourg 6.
Gold metal thousand troy ounces	--	2,364	1,661	Switzerland 1,499; United Kingdom 786.
Indium metal including alloys, all forms kilograms	4	4,672	1,262	Canada 1,385; Peru 1,255; U.S.S.R. 724.
Iron and steel:				
Ore and concentrate, except roasted pyrite	r131,657	133,727	132,571	Australia 64,094; Brazil 25,380.
Roasted pyrite tons	4,173	8,924	17,556	Mainly from Philippines.
Metal:				
Scrap	r3,081	1,802	1,440	United States 1,084; Australia 354.
Pig iron including cast iron	399	584	543	India 241; Australia 202.
Sponge iron, powder, shot	9	9	7	Mainly from Sweden.
Ferroalloys	90	179	191	Republic of South Africa 101; Taiwan 25.
Steel, primary forms	69	r112	160	Mainly from Australia.
Semimanufactures	41	r33	36	Republic of Korea 21; United States 4.

COMMODITY REVIEW

METALS[7 8]

Aluminum.—Japan, with an annual production capacity of 1.6 million tons, is the world's third largest producer of aluminum metal after the United States and the U.S.S.R. However, because of the increasing cost of energy, Japan's industry lost international competitiveness following the energy crisis of 1973. About 15,000 kilowatts of electrical energy is needed to produce one ton of ingot. Domestic electricity costs between Y9 and Y10 per kilowatt compared with overseas prices of Y1 to Y5. Additionally, because of the yen appreciation, the price of foreign ingot was around Y300,000 per ton compared with the Japanese producer price of Y371,000. In 1977, producers were operating at 74% of capacity, and each company was estimated to have a Y5 billion deficit. In its report, the Industrial Structure Council recommended that about 24% of the present capacity be frozen or partly scrapped during 1978-82 and holding production to 1.2 million tons in 1978; covering the difference in domestic production and demand for ingot by imported metal; a joint sales company be created to reduce competition between producers; and a tariff quota system for imported metal be introduced to raise revenue for subsidizing interest payments in frozen capacity.

Because of the economic problems associated with domestic aluminum production, the industry turned to overseas ventures. Construction began in July 1977 on a joint Japanese and Indonesian project to develop hydroelectric power and an aluminum smelter in the Asahan River area in northern Sumatra. Completion of first-stage construction was planned for 1986; however, completion may be delayed because of rapidly increasing financial outlays. In late 1977, Nippon Amazon Aluminum Co. (Tokyo) and Brazilian investors reached an agreement to set up a joint venture involving an alumina-aluminum complex in Belem at the mouth of the Amazon River. In another venture, Japanese and Venezuelan investors reached an agreement for a smelter with a production capacity of 280,000 tons of metal a year. The terms included that 160,000 tons of ingot was to be shipped to Japan starting in March 1978.

Total imports by Japan of bauxite were 5.3 million tons in 1977, compared with 4.3 million tons in 1976. Australia continued to be the principal supplier of bauxite for Japan's aluminum industry. In 1977, shipments of bauxite from Australia totaled nearly 3.5 million tons. About 1.2 million tons of bauxite was imported from Indonesia and about 520,000 tons was supplied by Malaysia. The remainder of the bauxite shipments and imports of alumina were from Guyana, Surinam, China, Greece, Trinidad, the United States, India, Brazil, and Guinea, in that order.

Imports of unwrought aluminum metal valued at Y110.9 billion in 1977 totaled 411,624 tons and were principally from New Zealand, Bahrain, Canada, Australia, and the U.S.S.R; imports of unwrought aluminum valued at Y31.2 billion were 126,657 tons, of which almost 50% were supplied by the U.S.S.R. Receipts of aluminum waste and scrap valued at Y16.1 billion during the year totaled 70,470 tons, of which 43,348 was from the United States.

Production of alumina by four companies in 1977 was 1.8 million tons, up 26% from the output in 1976. Alumina production was by Nippon Light Metal Co., Ltd., Showa Keikinzoku K.K., Sumitomo Aluminum Refining Co., and Mitsui Aluminum Industry Co. Production of primary aluminum metal by 14 smelters of 6 companies was 1.2 million tons in 1977, up 3% from that of 1976. Because of high inventories, the industry operated at 73.9% of capacity during the year compared with 61.6% in the previous year.

Production of super-purity aluminum metal was 4,700 tons in 1977, up 9% from the output in 1976. Production was by the Kambara smelter of Nippon Light Metal and the Kikumoto smelter of Sumitomo Aluminum.

Copper.—Copper is one of the important mineral resources of Japan, and mine output averages around 80,000 tons per year. Mine production was from 10 mines—7 in Akita prefecture (Hanaoka, Kosaka, Shakanai, Matsuki, Fukazawa, Osarezawa, and Minami-Furutobe) and 1 each in Hakkaido prefecture (Shimokawa mine), Iwate (Kamaishi), Hyogo (Akenobe), and Ibaragi (Hitachi). Late in 1977, Mitsubishi Metal Corp. announced the closure of the Osarusawa mine and the Matsuki mine in January 1978. The Osarusawa mine had

Digitized by Google

been operated for nearly 1,270 years, producing 70,000 tons of ore per month at the height of the operation in the 1950's. Current output level has been around 17,000 tons of ore per month, employing 220 persons. The Matsuki mine employs 160 workers and produces about 13,000 tons of ore per month. The company cited high operating costs, exhausted ore deposits, and weak formation as factors for the shutdowns.

Dowa Mining Co. was expected to invest Y3 billion in developing Ezuri mine, which contained 3 million tons of black ore grading 10.1% zinc, 3.32% lead, 0.89% copper, and 180 grams of silver and 1.3 grams of gold per ton of ore. Initial operation was scheduled for October 1979 with production of ore at 10,000 tons per month, to be raised to 18,000 tons the following year. To supplement domestic requirements, Japan imported 2.8 million tons of ore and concentrates valued at Y239.8 billion. Principal suppliers were Canada (855,895 tons), the Philippines (804,349), Papua New Guinea (362,231 tons), China (210,693), Indonesia (157,905 tons), Zaire (130,144 tons), Australia (127,233 tons), and Sabah (115,489 tons).

During the year, refined metal production totaled 934,000 tons and imports of unwrought metal totaled 272,000 tons, together valued at Y100.7 billion. Shipments in 1977 by major producers were as follows, in tons, with values in billion yen in parentheses: Nippon Mining, 229,344 (79.8); Mitsubishi Metal, 218,457 (78.9); Mitsui Mining and Smelting, 123,064 (39.3); Sumitomo Mining, 137,849 (46.9); Dowa Mining, 120,293 (40.9); Furukawa Mining, 74,880 (25.1); and Toho Zinc, 3,339 (1.2).

Producers continued to be plagued with sluggish demand, price reductions, deteriorating profits, and swelling inventories. Under the Nonferrous Stockpile Program, 20,000 tons of copper metal was purchased to help ease the supply-demand imbalance. In May 1977, copper inventories increased to 160,000 tons, and in December, the price for copper reached a low of Y320,000 per ton. In August, Mitsui Mining and Smelting and other smelters were successful in postponing the development of the Michiquillay copper mine in Peru. Also, Cobre Panama S.A. (Mitsui Mining, Mitsubishi Metal, and Dowa Mining) delayed exploration during the year of copper deposits at Petaquillay, and Dowa Mining sold its interest in the Chacarilla copper deposits in Bolivia to local investors. In addition, Japanese developers were involved with mining in Kinsenda and Musoshi, Zaire, and in Manut, Malaysia. The African operations were reportedly having financial difficulties, and the Malaysia venture was suffering from technical problems.

Iron and Steel.—Japan has the third largest iron and steel industry in the world, following the U.S.S.R. and the United States. More significantly, the country's production facilities are large, integrated, efficient, and modern. During December 1977, Tokyo Seitetsu closed down the last open-hearth furnaces in Japan. The Okayama Works had been operating five 120-ton open hearths, which were replaced by electric furnaces. Since the beginning of the decade, investments for plant and equipment by the steel industry averaged Y863.4 billion annually. Investments in 1977 totaled Y731.9 billion, which included Y82.7 billion for antipollution facilities.

Japan's industry has 100 basic oxygen furnaces (BOF's) with a collective annual capacity of 140.62 million tons, compared with 79 BOFs for the United States (80.07 tons per year), 45 for the U.S.S.R. (43.6 tons per year), and 36 for the Federal Republic of Germany (43.55 tons per year). There are 38 blast furnaces, each with a volume of more than 2,000 cubic meters. At yearend 1977, there were 684 electric furnaces, 130 continuous casting machines (34 for slab and 96 for bloom and billet), 23 hot-strip mills, and 70 cold-strip mills.

The industry is widespread throughout the country, but the highest concentration of main steelworks in Japan are in Kinki (18), Kanto (15), Chugoku (11), Chubu (9), Tohoku (5), Hokuriku and Kyushu (4 each), and Hokkaido and Shikoku (2 each). Japan's steel production of 102.4 million tons in 1977 was 5% less than that of 1976, and well below the peak production of 119.3 million tons in 1973. Japan trailed the U.S.S.R. and the United States with crude steel production of 146.7 million tons and 113.7 million tons, respectively, in 1977. Japan, however, continued to be the world's foremost exporter of steel with about 35.0 million tons in 1977, a decrease of 5.5% from shipments in 1976.

Five Japanese steel companies, headed by Nippon Steel Corp., were among the world's top 15 producers in 1977, with output of 32.4 million tons. The other top producers were as follows, in million tons: United States Steel, 26.1; British Steel, 17.2; Bethlehem

Digitized by Google

Steel, 15.1; Nippon Kokan, 13.8; FINSIDER, 12.9; Sumitomo, 12.5; Kawasaki, 12.5; August Thyssen, 11.5; National Steel, 8.5; Republic Steel, 8.4; Kobe, 7.4; Broken Hill, 7.3; and Inland Steel, 7.0.

Domestic mine output of iron sands, pyrite sinter, and iron ore concentrates constitutes about 1% of the total industry requirements. Nittetsu Kogyo announced it would close the Kamaishi mine, the only iron ore mine in Japan, in 1979 because of financial difficulties. During the year, 132,571,000 tons of iron ore was imported, primarily from Australia (47.6%), Brazil (17.9%), and India (13.5%). Japan's largest iron ore suppliers continued to be mainly Hammersley Iron Pty., Ltd., Mount Newman Iron Ore Co., Mount Goldworthy Mining Ltd., Robe River Mines, Ltd., and Broken Hill Pty., Ltd., of Australia; Rio Doce and Mineracoes Brasileiras Reunidas of Brazil; and the Mineral and Metal Trading Corp. of India.

Japan imported 1.5 million tons of ferruginous manganese ore, 1.5 million tons of manganese ore, 0.6 million tons of pig iron, and 1.4 million tons of iron and steel scrap, and 55.9 million tons of coking coal. Most of the coking coal was provided by Australia (44%), the United States (26.9%), and Canada (18.5%). About 130.9 million tons of iron ore was consumed for ironmaking. In 1977, consumption by the iron and steel producers included 84.2 million tons of pig iron, 34.6 million tons of iron and steel scrap, 43.8 million tons of coke, 62.7 million tons of coking coal, 7.9 million kiloliters of heavy fuel oil, 5.1 billion cubic meters of oxygen, 64.6 billion kilowatt-hours of electricity, 1.4 million tons of manganese ore, and 17.9 million tons of limestone.

During the year, crude steel production totaled 102.4 million tons. A breakdown of steel production, by type of furnace, was as follows, in million tons: Basic oxygen, 82.4; electric, 20.0; and open hearth, 0.4. About 98% of the total output was consumed for rolled products and the remainder for forgings and castings. Production of hot-rolled ordinary steel totaled 79.6 million tons and for hot-rolled special steel, 10.3 million tons. Production of ferroalloys in 1977 was 1.6 million tons.

Steel exports in 1977 were estimated at 34.9 million tons valued at $10.9 billion. Compared with 1976, the volume of exports decreased 5.5% but value increased 0.9%. The average export price per ton in 1977 was $312, compared with $294 in 1976 and $348 in 1975. Exports of ordinary steel products were 30.6 million tons; shipments of special steel products were 1.8 million tons.

Shipments totaling 12.9 million tons went to Southeast Asia, the largest market for Japan's steel industry. Exports to China increased by 29% to 4.5 million tons in 1977. Shipments to Taiwan and South Korea were 1.4 million tons and 1.9 million tons, respectively. Demand for Japanese steel products in the Middle East weakened, and exports to this area decreased 25% to 3.9 million tons. Exports to Europe were 4.7 million tons, including 1.3 million tons shipped to the U.S.S.R. Japanese steel exports to the United States totaled 7.6 million tons during the year.

Lead and Zinc.— Domestic mine production supplied about one-fourth of the total industry smelter output of lead and zinc. The major lead-zinc mines in Japan were Kamioko (Iwate Prefecture), Hanaoka (Akita), Hosokura (Miyagi), Kosaka (Akita), Nakatatsu (Fukui), Toyoha (Hokkaido), Osarizawa (Akita), Akenobe (Hyogo), Shakanai (Akita), Furutube (Akita), and Oppu (Aomori).

The Metal Mining Agency of Japan conducted core drilling totaling 14,628.8 meters on eight projects in its domestic exploration and development program. As a result of its geological survey, the agency discovered a mineralized zone of Kuroko (black) ore in the Hokuroku area, a zinc-rich mineralized zone in the Nakatatsu area, and lead-zinc veins in the Bantan area. Private companies have been conducting exploration for Kuroko ore as well, particularly in the Hokuroku and Iwami areas. New zinc deposits were discovered at the Kamioka and Nakatatsu mines, and a high-grade, vein-type deposit at the Toyola mine was found in Hokkaido. Dowa Mining began developing the Ezuri mine, which contains about 10% zinc in Kuroko ore. Toho Zinc, however, suspended its plan to develop a lead-zinc mine in Guatemala.

Because of the yen revaluation and the low prices for lead and zinc, domestic mining operations were forced to lay off workers during 1977. The major producers of lead and zinc in Japan were Mitsui Mining & Smelting Co., Ltd., Toho Zinc Co., Ltd., Nippong Mining Co., Ltd., Mitsubishi Metal Corp., the Dowa Mining Co., Ltd., and Sumitomo Metal Mining, in that order. Mitsui Mining suffered the largest deficit in its

Digitized by Google

operations, amounting to Y4,593 million, because of low zinc prices. Toho Zinc had a deficit of Y2,750 million, followed by Sumitomo Metal with Y2,181 million and Dowa Mining with Y1,185 million. Nippon Mining had a net profit of Y3,109 because of its oil operations and the higher yen value to the dollar. Mitsubishi Metal's net profit of Y1,481 million was the result of sales of bonds, securities, and real estate. Since 1974, annual zinc production has exceeded sales, and in 1978, sales of zinc ingot were expected to drop 2.2% to 765,000 tons. The price for zinc fell by about Y30,000 to Y174,000 per ton in December, chiefly from markdowns by foreign zinc ore suppliers and the rising yen value. Inventories of zinc reached a peak of 210,000 tons in May 1977.

Despite the severity of the economic conditions, primary zinc production increased 5% in 1977. During the year, production of electrolytic zinc totaled 472,233 tons; that of high-purity zinc, 130,293 tons; and that of distilled metal, 175,880 tons.

During the year, Mitsui Mining was completing improvments at Kamioka and Takehara. Hachinohe Smelter was installing a power plant that will utilize waste gas from its facility, and Akita Smelting was testing a decadmium purification process at its Iijima smelter.

Magnesium.—Production of magnesium metal in 1977 was by Furukawa Magnesium Co., Ltd., and Ube Kosan, Ltd. Total industry production capacity was 12,500 tons per year (Furukawa, 7,000 tons and Ube, 5,500 tons). Both producers use the Pidgeon process, utilizing domestic dolomite for metal production. Recovery of secondary metal during the year was about 7,600 tons, equivalent to about 80% of primary metal output.

Domestic consumption of magnesium averaged about 1,800 tons per month, and the shortfall between supply and demand is met by imported metal. Imported metal prices range between Y530,000 and Y540,000 per ton, compared with domestic producers' price of Y570,000 per ton. Should demand for can stock rise, a sharp increase in magnesium imports could adversely affect the small Japanese producers.

Manganese.—In 1977, domestic output of manganese ore from 17 mines was about 126,000 tons containing about 32,800 tons of manganese metal. Most of Japan's requirement for manganese, however, was met by imports supplied mainly by Australia, the Republic of South Africa, and Mexico. Approximately 97% of the manganese is used in the iron and steel industry. The remainder is consumed in battery manufacture, chemicals, and miscellaneous uses.

Production of electrolytic manganese during the year totaled 7,267 tons, compared with oxide production of 28,549 tons. Metal output was by Tekkosha Co., Ltd., and Chuo Denki Kogyo K.K., with a combined annual capacity of 14,000 tons. Production of manganese oxide was by Mitsui Mining & Smelting and Daiichi Carbon. Production of ferromanganese and silicomanganese by the iron and steel industry was 527,400 tons and 333,700 tons, respectively.

The price of domestically produced manganese metal is Y450,000 per ton. The base cost for imported metal was Y270,000 to Y280,000 per ton, excluding Y35,000 to Y36,000 for freight duty of 8% and trading charges. Total price of imported metal per ton was about Y100,000 less than the cost of domestic manganese.

MITI was planning to form a committee in 1978 to study exploitation of deep sea manganese nodules. Appointments to the committee were to be made from steel companies, refining companies, academia, and from government organizations.

Molybdenum.—Domestic production of molybdenum by two small mines remained nominal. Imports of molybdenum ore during the year were from the United States, the Federal Republic of Germany, South Korea, and Chile; in that order. Receipts of molybdenum concentrates were 16,505 tons.

The bulk of molybdenum was consumed in the production of molybdic oxide and ferromolybdenum. During the year, the iron and steel industry produced 3,705 tons of ferromolybdenum. Production of high-purity molybdenum metal totaled 275 tons.

Molybdenum is used in the production of high-tensile-strength steels, output of which fell 12% in 1977. Demand for molybdenum was expected to increase as a result of overseas sales of steels for large-diameter pipes to the Soviet Union and other countries.

Nickel.—For lack of indigenous resources, Japan imported all of its nickel needs. Metal production was by Sumitomo Metals and Mining, Shimura Kako, and Nippon Mining. Consumption of nickel was estimated at 19,700 tons, distributed as follows: Plating, 32%; special steels, 14%; cast steel alloys and electronics, each 10%;

Digitized by Google

copper and coinage, each 4%; and other uses, 16%.

In terms of contained nickel, the quantity of ferronickel consumed was more important than nickel metal consumption. Pacific Metals Co., Ltd., Japan Metallurgical Industries, Nippon Mining Co., Sumitomo Metal Mining Co., and Shimura Kako Co., Ltd., were the five companies that produced ferronickel. As in the past, most of the ferronickel was consumed (56,982 tons) in the production of specialty steel and the remainder (17 tons) was used for cast steel.

Shimura Kako reached an agreement with its labor union in 1976 to transfer its nickel division from Tokyo to Date, Hokkaido. Preparation for construction of the nickel refinery at Date began in June 1977. The refinery was to be constructed adjacent to the company's existing ferronickel plant and was to have an annual production capacity of 10,000 tons of electrolytic nickel and 1,000 tons (nickel content basis) of nickel sulfate. The new plant, expected to be completed in April 1978, will utilize Inco's newly developed electrowinning process and replace the 7,200-ton-per-year nickel refinery in Tokyo. Total cost of construction was expected to be over Y10 billion.

Titanium.—Production of titanium sponge in 1977 by Osaka Titanium Co., Ltd., and Toho Titanium Co., Ltd., totaled 6,395 tons. The two companies have a combined rated output capacity of 950 tons per month, indicating that total production during the year was only 56% of total capacity. Titanium metal is used primarily for its corrosion-resistant properties. While consumption of titanium was on the upturn during 1972-74, demand slackened in 1975 and 1976 due to protracted orders for equipment for desalination, petrochemical, and caustic soda plants as a result of the prolonged recession.

In 1977, shipments of titanium ore and concentrates to Japan totaled 495,967 tons. Major suppliers were Australia (150,289 tons), Malaysia (130,024 tons), India (82,277 tons), Sri Lanka (41,219 tons), and Canada (92,104 tons). Only a small portion of the imports was used for metal production. Japan, on the other hand, is a prominent world producer of titanium dioxide (titania), using imported ilmenite as a raw material. Some rutile and anatase is also imported.

Tungsten.—Domestic production of tungsten concentrate in 1977 totaled 975 tons and was produced by Kaneuchi Mining (Kaneuchi and Fujigawa), Nittetsu Mining Co., Ltd. (Yaguki), Awamura Mining (Otani), Tanaka Mining (Kuga), Nittetsu Mining (Yaguki), Chitose Mining (Takatori), Mitsubishi Metal (Ikuno), and Chugai Mining Co., Ltd. (Tsumo). The largest production was by Kaneuchi Mining (393 tons), followed by Nittetsu Mining (300 tons) and Awamura Mining (170 tons). Imports of tungsten ore totaled 3,247 tons. The largest suppliers were South Korea (948 tons), Thailand (480 tons), Peru (414 tons), and Australia (399 tons). The remainder of tungsten imports were from Canada, China, Portugal, Zaire, Mexico, and Bolivia.

Demand for tungsten in 1977 was estimated at 3,821 tons, distributed as follows, in tons: Ferrotungsten, 520; synthetic scheelite, 751; tungsten metal, 2,544; inorganic chemicals, 4; and other, 1.

Other Metals.—Japan produced only a small quantity of antimony ore; virtually all antimony requirements are met by imports of ores and concentrates and metal. Output of metal in 1977 was by Hibino Metal Industries, by Nippon Mining and Concentrating, and by Mikuni Refining. Production of antimony oxide was by Nippon Mining and Concentrating, Sumitomo Metals & Mining, Hibino Metal industries, Mikuni Refining, and Japan Mining, in that order.

Production of bismuth metal, a byproduct of lead refining, was 698 tons in 1977. The largest producers were Mitsui Metals and Mining, Dowa Mining, and Sumitomo Metals & Mining, in that order. Domestic consumption of bismuth was estimated at 350 tons of which the largest use was as a metallurgical additive, followed by condensers, low fusing alloys, catalysts, and other.

Japan and the United States are the world's two leading producers of cadmium, a byproduct of zinc smelting. The uses for cadmium were in batteries, pigments, and as a stabilizer for polyvinyl chloride. Production of cobalt metal, a byproduct of copper and nickel refining, totaled 1,093 tons in 1977 compared with 515 tons in 1976. Most of Japan's requirement for cobalt is met by imports.

The estimated consumption for cobalt in 1977 was 2,455 tons compared with 2,996 tons in 1976. About 45% of the total use of cobalt in 1977 was for the production of permanent magnets for small speakers used in radios and television sets. The remainder of cobalt consumption was distributed as

Digitized by Google

follows, in tons: Steel alloys, 557; ultrahard alloys, 112; catalysts, 107; and other uses, 562.

Japan is the world's largest producer of selenium. Selenium as well as tellurium was recovered as a byproduct in the processing of slimes generated from electrolytic copper refining. The major uses for selenium were in electronics and photocopier components, glass manufacture, chemicals, and pigments. A growing use for selenium was as an additive to stainless steel to improve machinability.

Japan is a major producer of indium, and output in 1977 was estimated at 8.0 tons, including recovery from recycled indium products. Toho Zinc was the largest producer with an annual production of 3.8 tons. Nippon Mining had an average monthly output of 250 kilograms, with a peak capacity of 280 kilograms. Dowa Mining began recovering indium in June 1976 from slag generated by gallium processing. Dowa Mining was capable of producing 50 kilograms per month. Tamaka Electronics Industries, an associated company of Mitsui Metals & Mining, has a monthly capacity of 50 kilograms of indium. Indium was used in electronic components and solders and other alloys.

During 1977, Japan produced 1.3 million troy ounces of gold and 38.2 million troy ounces of silver. Output of gold was derived mainly from the smelting of imported nonferrous ores. Recovery of silver was at a slightly higher level than in 1973-76; about one-third was from domestic ores. Domestic production of platinum and palladium was nominal, less than 1,000 kilograms, and Japan has had to import these noble metals in one form or another.

Japan also produced other metals, usually of high purity and generally in quantities significant by world standards. Refined metals and compounds produced, mostly from imported materials, included chromium, germanium, rare-earth metals, silicon, tantalum, and uranium.

NONMETALS[9]

Cement.—Japan ranks with the United States and the U.S.S.R. as one of the foremost producers of cement in the world. Total industry capacity to produce cement was 110 million tons per year. However, total output of cement during the year was only 62% of rated capacity. Production of cement was by 22 companies. Kyushu District had 19 plants, Kanto Shinetsu had 14, Kinki had 8, Chugoku had 7, Tohoku and Tokai-Hokuriku had 3, Hokkaido and Shikoku each had 2, and Okinawa had 1.

The top two producing companies were Onoda Cement Co. and Nihon Cement Co., which together accounted about 17% of total sales. Other top producers were Mitsubishi Mining & Cement Co., Sumitomo Cement Co., and the Industries, Ltd. Other large companies include Chichibu Cement Co., Osaka Cement Co., Tokuyama Soda Co., Toyo Soda Mfg. Co., and Denki Kagaku Kogyo Co.

In November 1975, cement manufacturers formed a production cartel to provide temporary relief to the industry, which suffered from slackened demand resulting from curtailment in construction projects since 1974. In 1976, 20 producers were member companies of the Cement Association of Japan. By binding together, the manufacturers of cement could attempt to mollify competition, make adjustments in production levels, and negotiate higher prices for cement. Production in 1976 was pushed back to the 1972 level and a similar cutback was effected for June-December 1977. Domestic sales in 1977 totaled 69.5 million tons. To cover the domestic slump, the industry pushed for overseas trade, and exports chiefly to Southeast Asia and the Middle East reached about 6.7 million tons. Total sales in 1977 of concrete aggregate were about 76 million tons.

To cope with soaring energy costs, producers halted operation of wet kilns in favor of dry kilns which use less fuel; conducted research and development on new suspension preheaters for energy savings as well as for pollution control; and branched out into other industrial lines, such as lightweight aggregate, ground preparation, and inorganic construction materials.

Fertilizer Materials.—Japan's chemical fertilizer industry is one of the largest in the world. In terms of nitrogen fertilizers, Japan ranks fourth in world production after the United States, the U.S.S.R., and China. The industry's output of calcium and phosphatic fertilizers was large, while that of potassic fertilizers was relatively insignificant. Japan's production of fertilizer materials also included large tonnages of ammonia; ammonium sulfate and chloride; calcium carbide, cyanamide, superphosphate; and fused magnesium phosphate. Japan's fertilizer industry has been traditionally

Digitized by Google

export oriented, exporting 70% of the urea and ammonium chloride production and most of the ammonium sulfate production to Southeast Asia, China, and Latin America.

Japan's fertilizer industry has been adversely affected by low plant operation rates, international competitiveness, narrowing export markets, and increased costs. Since 1975, there has been a marked deterioration in profits, especially for nitrogen fertilizers. Although the foreign market prices for ammonium sulfate and urea were on an upward trend, the Japanese export prices were still insufficient to cover the added cost of energy and other raw materials for production. Significantly, the price of naphtha, the feedstock most widely used for urea production, rose nearly fivefold after the 1973 oil crisis. To worsen the situation, Japanese exports of fertilizers have sharply decreased during 1975-77.

In an attempt to remedy the bleak picture, the industry began planning to reshape its structure, exploit new markets, revamp its distribution system, and retire surplus or outmoded production equipment. The Japan Urea and Ammonium Sulphate Industry Association recommended at year-end 1977 reduction of total industry capacity—20% for ammonia and 40% for urea. Also, the Japan Phosphatic and Compound Fertilizer Manufacturers' Association recommended a 20% reduction in phosphoric acid capacity. MITI was forming a chemical fertilizer committee at the Industrial Structure Council to consider plans for scrapping or freezing industrial facilities.

Magnesium Compounds.—Japan's capacity to produce magnesium oxide from seawater was estimated at 750,000 tons per year. The largest producer was Ube Chemical Industries, which had about 58% of the total output capacity, followed by Shin-Nihon Chemical Industries Co., Hokuriku Seien Kogyo K. K., and Nihon Kasui Kako Co. Imports of magnesite and magnesia clinker during the year were 5,567 tons and 46,096 tons, respectively. By far the largest use for magnesia was in the production of basic refractories for heat insulating bricks for lining metallurgical furnaces, of which the largest consumption was in the iron and steel industry. The remainder of the magnesia consumption, about 10%, was in agricultural and chemical processing applications.

Salt.—Japan's salt production, all from evaporites, was 1,056,000 tons in 1977, compared with imports of 6,415,320 tons. The largest shipments were from Australia and Mexico. The remainder was from China and Canada. In 1975 both Australia and Mexico renegotiated price increases for salt exports to Japan. The producers claimed that higher prices were needed to make a reasonable profit. The average unit value of imports in 1977 from Australia was about $18.08 per ton, compared with $16.15 per ton from Mexico.

Aside from human consumption, salt is needed in Japan mainly by the chlor alkali industry. Throughout 1977, the chlor alkali industry consisting of 36 firms with 54 plants operated at around 60% of capacity to produce 2.7 million tons. The industry was faced with depressed demand for caustic soda in 1977, as well as with the Government decree for the industry to switch production technology from mercury cells to a nonmercury technique by March 1978. Most producers chose the asbestos diaphragm technique. The change in technology was expected to cost between Y600 and Y800 billion. In addition to declining profits and the prospect of large capital outlays to change technology, the industry faced technical problems in the switchover.

Because of depressed demand, low prices (Y54,000 per ton in 1977 compared with Y53,000 per ton in 1976), and yen revaluation, the Government postponed the production process switchover deadline. While 61.3% of the production capacity had changed to nonmercury cells, the remaining plants, with a total capacity of 1.8 million tons per year, could defer immediate conversion.

MINERAL FUELS

Coal.—Japan's coal mining industry reached its peak in 1960 when output exceeded 55 million tons and about 660 collieries were in operation. Subsequently, low-priced oil rivaled coal as Japan's primary fuel source, and the coal industry began closing mines and reducing employment year after year. By 1977, domestic production of coal by 8 companies with 29 collieries with 20,000 workers, was 18.3 million tons. Production during the year was by Mitsui Mining & Smelting Co., Ltd.; Hokkaido Colliery & Steamship Co., Ltd.; Taiheiyo Coal Mining Co., Ltd.; Mitsubishi Coal Mining Co., Ltd.; Sumitomo Coal Mining Co. Ltd.; Matsushima Coal Mining Co. Ltd.; Joban Coal Mining Co., Ltd.; and Kaijima Coal Mining Co., Ltd.

Digitized by Google

The lack of domestic capacity to meet rising demand forced users to depend on overseas supplies. About 15 million tons of steam coal was imported to meet the annual estimated consumption of 22 million tons. Japan imports over 60 million tons of coal annually; the overwhelmingly large share is for metallurgical use.

Petroleum.—Japan's production of crude oil remained of little consequence, amounting to only 4.3 million barrels in 1977.[10] The cost for all fuels imported was $31,150 million, of which $25,791 million was for petroleum. There were 49 petroleum refineries in operation in Japan with a total crude oil distillation capacity of 5,940,360 barrels per stream-day (bpsd). Thirty-eight refineries (5,379,800 bpsd) were on the Pacific coast, five refineries (147,560 bpsd) on the coast of the Sea of Japan, three refineries (205,000 bpsd) in Hokkaido, and three refineries (208,000 bpsd) in Okinawa. The large concentration of refineries on the east coast reflects the location of the large consuming areas, harbors, and advantageous weather conditions.

As of yearend, Japan had 49 refineries owned by 31 companies, with a total atmospheric crude distillation capacity of 5,940,360 barrels per stream-day. Corresponding downstream capacities were as follows, in thousand barrels per day: Vacuum distillation, 1,858; catalytic cracking, 343; catalytic reforming, 598; middle distillates hydrodesulfurization, 1,288; fuel oil desulfurization, 1,281; hydrocracking, 13; lube oil solvent extraction, 72; lube oil solvent deasphalting, 49; lube oil solvent dewaxing, 61; sulfur recovery, 7,687 tons per day; and liquefied petroleum gas recovery, 24,879 tons per day.

Total crude oil throughput in 1977 was 4,284,000 barrels per stream-day, of which 4,276,000 was imported. Total throughput was 0.8% above the level of the previous year. Petroleum products produced during the year totaled 235,336,000 kiloliters, of which the largest volume was fuel oil, followed by naphtha, kerosene, jet fuel, lubricating oil, and other.

The Mineral Industry of Kenya

By Janice L. W. Jolly[1]

Kenya's mineral production, excluding refined petroleum products, contributed more than $90 million[2] to the 1977 gross domestic product (GDP) valued at $3.9 billion at current prices. Kenya's economic growth continued through 1977, and its GDP grew 7.3% at constant 1972 prices.[3] Manufacturing output, including metal and petroleum products, increased 15% in volume in 1977, with the number of people in wage employment rising over 8%. Employment in the mining and quarrying sector was projected to increase rapidly to 10,000 persons by 1978. Buoyant domestic demand more than compensated for the decline in exports to Kenya's African neighbors, resulting from termination of the East African Community (EAC) and the consequent border closure with Tanzania. Public- and private-sector purchases of transportation equipment in the wake of the disintegration of the EAC rail and airways corporations accounted for nearly 40% of the increase in capital formation in 1977. Inflation of about 13% continued to be a problem.

Kenya received a $10 million credit from the International Development Association (IDA), a World Bank affiliate, for development of small-scale industries. The credit would be used for improvement and construction of factories and workshop clusters in Eldoret and Nairobi. Over the past 10 years, the World Bank has contributed financing for more than 40 projects in Kenya, with a total commitment of about $650 million.[4] The U.S. Agency for International Development (AID) also approved a loan of $13 million as well as a grant of $400,000 for construction of roads in western Kenya. The Kenyan link road with Sudan was to be financed by Norway and would cost about $8 million. The 230-kilometer road would be constructed between Lodwar in Kenya and Juba in southern Sudan.

Kenya Power Co. Ltd. was starting work on the geothermal deposits in the Okaria zone, which was expected to produce 170,000 kilowatts of energy per year. The project was estimated to cost $60.3 million and was being financed partly by long term loans from the World Bank and Commonwealth Development Corp. and partly by the company itself, which is owned by the Kenyan Government. Kenya's geothermal resources were estimated at 9 megawatts proven and 170 to 500 megawatts potential. Of Kenya's total 300 megawatts of installed electricity, 80% was oil-fired and 20% was hydroelectric. Kenya had contracted with the United Nations for a 1-year energy survey that was to focus mostly on rural applications. Alternatives to charcoal cooking were being sought in an effort to slow deforestation.

The Canadian Government agreed to loan $1.1 million to provide assistance to the Kenyan Mines and Geological Department in carrying out an airborne geophysical survey in which Canadian firms were to provide technology and equipment. The Canadian firm Terrasurveys would carry out magnetic and radiometric surveys over the coastal mineralized belt and selected parts of Nyanza and Western Provinces. Ground explorations were to follow. In addition, the Austrian company Austromineral was to map a 25,000-square-kilometer area in Taita-Taveta District with known deposits of asbestos, graphite, kaolin, and assorted gem stones. Marketing and processing studies were also to be done by the Austrian group.

Digitized by Google

PRODUCTION AND TRADE

Mineral production in 1977 consisted of petroleum products produced from imported crude oil; limestone, limestone products, clinker, and cement, valued at $67 million; soda ash and salt, valued at $12.8 million; fluorspar, valued at $11 million; and gem stones, valued at $3.6 million. Other minerals of lesser significance produced for local use included clays, corundum abrasives, calcite, carbon dioxide, diatomite, feldspar, guano, gold, magnetite, and vermiculite.

Cement production at 1,144,429 tons was 16% above that of 1976. Cement shortages in parts of the country were becoming a problem, and the industry was in the process of expansion. The local price of cement was about $3.25 per 50-kilogram bag, although in western Kenya the price was somewhat higher. Cement exports for the first 6 months of 1977 were valued at nearly $11 million.[5]

Petroleum imports made up 12.8% of the total import value of $1.1 billion for 1977. East African Oil Refineries Ltd. (EAOR) at Mombasa processed about 18.7 million barrels of crude oil imported from Iran (35.1%), Saudi Arabia (34.9%), Qatar (21.5%), and Abu Dhabi (8.5%). Refined petroleum products exports made up 16% of the total export value of $1.4 billion, going to Tanzania, the Seychelles, Réunion, the People's Democratic Republic of Yemen, the Comoros, Italy, Singapore, Djibouti, and Japan.

The United States accounted for about 6% of Kenya's foreign trade. In 1977, the United States ranked fifth as a supplier of goods to Kenya and fourth as a purchaser of Kenyan exports. Fluorspar valued at about $1 million was exported to the United States in 1977. Imports from the United States included fertilizers valued at $3.1 million.[6]

The breakup of the EAC and the closure of the Tanzanian border precipitated a sharp drop in trade between the three former partner States of Kenya, Uganda, and Tanzania. Trade between Kenya and Tanzania was the most severely affected; Kenya's imports from Tanzania dropped 88.5%. Kenya's 1977 exports to Uganda, Rwanda, Sudan, Zambia, Somalia, Egypt, and Burundi included salt, cement, and petroleum products. The trade route between Zambia and Kenya was also interrupted by the Tanzanian border closure.

Table 1.—Kenya: Production of mineral commodities

(Metric tons unless otherwise specified)

Commodity	1975	1976	1977[p]
METALS			
Beryl, gross weight	NA	1	--
Copper, mine output, metal content	70	(1)	--
Gold, mine output, metal content, troy ounces	r98	37	135
Iron and steel: Iron ore, gross weight	16,800	20,784	16,000
Lead, mine output, metal content[e]	1,100	480	--
Silver, mine output, metal content, troy ounces	84	118	--

COMMODITY REVIEW

METALS

Columbium.—Of Kenya's pyrochlore occurrences, the Mrima carbonatite complex near Mombasa has received the most attention and has the most potential. The French firm Péchiney Ugine Kuhlmann was reportedly continuing an exploration and sampling program around the Mrima area. Gross reserves proven previously by Anglo American Corp. and the Kenyan Mines and Geological Department were given as 50.6 million tons with an average of 0.67% Nb_2O_5 to a depth of 30 feet over 87% of the hill. Four varieties of pyrochlore were described as occurring in the weathered rock capping; the most abundant was a barium pyrochlore, pandaite. A second variety was the brown, translucent, strontium-bearing type, while a third contained titanium in quantities up to 7.5%.[7]

Lead, Zinc, Silver.—At yearend, the Kenya Mining Industries Ltd. lead, zinc, and silver mine and treatment plant at Kinangoni was being offered for sale.[8] The receiver and manager of the mine was empowered to offer the sale of the mine en bloc. The mine was closed in early 1977. Reserves had been estimated at 5 million tons when mining began in 1973. Geomin of Romania, in partnership with Industrial and Commercial Development Corp. (ICDC) of Kenya, had mined out 2 million tons of ore. Metallurgical, water, and management problems brought about the closure.

NONMETALS

Barite.—Mineral Mining Corp. Ltd. produced barite from its mine located 50 miles from Mombasa. Production at a rate of about 2,000 tons per month provided feed for a new 24,000-ton-per-year screening and washing plant. The plant capacity is to be increased to 50,000 tons per year by 1979 with installation of a new flotation circuit.[9]

Carbon Dioxide.—Natural carbon dioxide was commercially exploited in two locations in Kenya. The gas was sold compressed for use in Kenya's bottling industry and as dry ice for use as a refrigerant. The two commercial wells have been producing since the early 1950's.

Cement.—The European Investment Bank, under the Lomé Convention agreement, loaned East African Portland Cement Co. Ltd. $3.4 million to finance expansion of its Athi River plant near Nairobi. Pro-

Digitized by Google

duction capacity was to be increased 50% to 375,000 tons per year. East African Portland Cement was owned 50% by the Kenyan Government, 20% by private Kenyan shareholders, and 30% by Associated Portland Cement Manufacturers Ltd. of the United Kingdom and Cementia Holding AG of Switzerland. Kenya was using about 44% of its present cement production. Expansions of the Athi River plant and the Bamburi Portland Cement Co. Ltd. plant at Mombasa were expected to add 330,000 tons per year to the available supply by 1980. Bamburi Portland Cement's production at yearend 1979 was expected to be 1,160,000 tons, mostly for export. At yearend, a cement shortage persisted in northern Kenya, caused mostly by transportation problems.

Fluorspar.—Fluorspar Co. of Kenya Ltd. mined fluorite at its Kerio Valley mine, producing 124,000 tons valued at $11 million. Acid-grade fluorspar made up 85% of total production.[10] Development of reserves from both replacement and vein-type fluorite deposits continued.

Gem Stones.—Gem stone production included green garnet (locally called tsaverite), rhodolite, ruby, and sapphire. Also attracting interest were the garnets derived from areas along the Umba River near the Tanzanian border. Gem stone prospecting was reportedly increasing. The gem stone belt in Taita-Taveta District of Coast Province continued to be the major source of gem stones.

Salt.—Salt Manufacturers (Kenya) Ltd., a new firm, announced that Kenya would soon be self-sufficient in salt and would sell surplus for export. The company is to produce nearly 100,000 tons of marine salt when phase 2 of its newly acquired saltfields near Malindi, covering nearly 60 square kilometers, becomes fully operational within about 2 years.[11] About 12,300 tons of refined salt was produced in Kenya during 1977.

Soda Ash.—Soda ash continued to be produced from Magadi Soda Co.'s deposits at Lake Magadi in Rift Valley Province in southern Kenya. Dredging operations recovered about 109,000 tons of soda ash valued at $11 million during 1977.

MINERAL FUELS

Petroleum.—The 450-kilometer-long, 14-inch-diameter pipeline running from the EAOR petroleum refinery at Mombasa to a terminal in the industrial area of Nairobi was completed in November. The oilline is to be officially in service sometime during the first half of 1978, and an agreement was signed between Kenya Oil Pipeline Co. Ltd. (KPCL) and petroleum companies. The pipeline will deliver 90,000 gallons per hour. Costing about $100,000, it was built by firms from the United Kingdom and Japan. Materials used in the project came from the United Kingdom, Japan, the United States, and India.

Total Kenya, operator for the group Cie. Française des Pétroles (CFP)/Total (70%) and Elf-Aquitaine (30%), employed the exploration drillship *Le Pelerin* in a petroleum search offshore near Mombasa. The exploration permit covered over 5,000 square kilometers at a depth of nearly 1 kilometer.

The Mineral Industry of North Korea

By E. Chin[1]

The year 1977 marked the end of the fourth economic development plan (1971-77). It was generally believed that the Government's goals were overly ambitious, and the various sectors of the economy did not fulfill their goals;[2] hence, the plan, originally covering the period 1971-76, was extended another year. During this period, which was North Korea's first 7-year plan period, North Korea's development was hampered by recession and its inability to meet payments on the country's outstanding foreign debt. In 1973, the Government initiated new policies to achieve economic parity with its counterpart in the south, the Republic of Korea. In this plan, the Government began to import modern industrial equipment from market economy countries as well as from its allies. During 1974, purchases from market economy countries totaled $786 million, of which $253 million was for machinery. In 1975, these purchases were $560 million and in 1976 were reduced to $300 million. Beginning in 1975, however, the Government was unable to meet payment of part of its outstanding debt, which was then estimated at $1.3 billion and has escalated as a result of purchases in 1976-77. Reportedly, the People's Republic of China and the U.S.S.R. began reducing economic aid to North Korea. Also, the Government began to negotiate a repayment formula for its financial obligations to European and Japanese banks. While it was believed that agreement was reached on rescheduling payment on overdue debts, no official announcements were made. North Korea, however, was believed to have successfully negotiated terms of 2 to 5 years on repayment of overdue notes at an annual interest rate of 7.3% to 8%.

The fifth economic plan, which was the second 7-year plan (1978-84), calls for doubling and even tripling some output targets. While the present plan was "designed to further the strength of the country both in terms of economic independence and in strengthening the scientific-technical levels," the new economic plan "proposed high goals without precedent" and "is a grand economic program which anticipates rapid development."

The Government characterized the basic tasks of the second 7-year plan as follows: "During the new long-term plan period, we must further step up Chuche in the people's economy to permanently establish a strong source of fuel, motive power, and raw material bases in the nation. We must further strengthen the self-sufficient system of our economy by creating new industrial sectors, and by developing the economy with more diversity and comprehensiveness."[3]

During the new plan period, "industry will gallop at a highly accelerated rate, on the average of 12.1% annually." The proposed production goals of the fifth economic plan as well as the targets of the third and fourth plans were as follows, in million tons unless otherwise specified:

Sector	1970	1977	1984
Iron ore	7.2	NA	16.0
Pig iron	2.3	3.5-3.8	6.4-7.0
Steel:			
Crude	2.2	3.8-4.0	7.4-8.0
Rolled	1.7	r2.8-3.8	5.6-6.0
Nonferrous metals	.16	.45	1
Cement	4.0-4.5	7.5-8.0	12-13
Chemical fertilizers	1.5	2.8-3.0	5
Magnesium clinker	NA	1.6	NA
Coal	27.5	50-53	100
Electricity billion kilowatt-hours	16.5	28-30	56.60

rRevised. NA Not available.

Digitized by Google

While the second 7-year plan projects slower growth, it has been conjectured that targets in key areas appear unrealistic.[4] Since 1975, North Korea has been cut off from additional credit from market economy countries, and no major import contracts have been signed. The goals for electric power, steel, and cement will probably not be met owing to the country's inability to import the required machinery and equipment.

PRODUCTION[5]

North Korea produces a variety of mineral commodities. Important minerals extracted are anthracite and bituminous coal, graphite, lead-zinc, magnesite, magnetite, and tungsten. In fact, North Korea is believed to be the world's second largest producer of magnesite, anthracite, and graphite; it is a medium-size producer of lead and zinc and a significant steel producer, following only Japan, China, and India in the Orient. Apatite, barite, copper, gold, and talc also are produced. The country has large reserves of coal, but petroleum and natural gas have not been discovered.

All of the country's mineral industries are State-owned. Moreover, the Government of North Korea does not publish mineral production data for dissemination. The production data given in table 1 denote a relative order of magnitude of North Korea's output of minerals and fuels. Output by the mineral sector comprises about 20% of the country's gross national product (GNP).

Government ministries and agencies which provide guidance and assistance to North Korea's mineral industries include the Ministry of Building Materials Industry (cement and construction), the Mining Industry Committee (coal and general mining), the General Bureau of Coal Industry, the General Bureau of Geology (surveying), the Ministry of Metallurgical Industry, and the Ministry of Chemical Industry.

Bituminous and lignite	do.	8,000	8,000	8,500
Total	do.	40,000	41,000	43,000
Coke	do.	2,200	2,500	3,000

[p]Preliminary. [r]Revised.

[1]In addition to the commodities listed, a variety of other mineral commodities may be produced, but available information is inadequate to make reliable estimates of output levels. These include (but are not limited to) antimony, arsenic (in arsenopyrite), asbestos, beryl, bismuth, boracite, kaolin (china clay), chromium, cobalt, columbite, germanium, indium, lithium minerals (lepidolite), manganese ore, mica (phlogopite), molybdenite, monazite, nickel and/or ferronickel, selenium, tellurium, titanium minerals (ilmenite and rutile), zircon, and a variety of crude construction materials including miscellaneous clays, glass sand, building sand, stone (crushed and dimension), and gravel.

[2]Includes granulated iron.

TRADE

Although all trade transactions are conducted by the Government, it does not publish official foreign trade data for dissemination. Trade data, given in tables 2 and 3, are derived from published import-export information of selected trading partner countries.

North Korea's total trade value in 1977 was probably around $1.0 billion to $1.5 billion. The country's chief exports are manufactured light industry goods, some raw materials, and foodstuffs. The leading mineral exports include iron ore, pig iron, steel semimanufactures, lead and zinc, tungsten, cement, magnesite, and talc. The country imports machinery and transportation equipment, mineral fuels, foodstuffs, and selected raw materials such as coal, coke, and chromium and manganese ores. North Korea's main trading partners were China, Japan, and the U.S.S.R., not necessarily in that order. Other trading partners have included Australia, Canada, Israel, New Zealand, European countries, and member countries of the Council for Mutual Economic Assistance.

The principal Government corporations that handle North Korea's trade in science and technology transfers, minerals, and value-added mineral products include Korea Complex Equipment Export Corp., Korea JEIL Equipment Import Corp., Korea Industrial and Technical Corp., Korea Technical Corp., Korea Machinery Export Corp., Korea Machinery Import Corp., Korea Minerals Export and Import Corp., Korea Ferrous Metals Export and Import Corp., Korea Nonferrous Metals Export and Import Corp., Korea Chemicals Export and Import Corp., Korea Building Materials Export and Import Corp., Korea Ponghwa Trading Corp., Korea Kwangmyong Export and Import Corp., Korea Daesong Trading Corp., Korea P'yongyang Trading Co., Ltd., and Korea Okryu Trading Corp.

COMMODITY REVIEW

METALS

Iron and Steel.—The current production capacity of iron ore and concentrate was around 11 million to 12 million tons. About 60% of the total production was from the Musan mine, which has an annual output capacity of 6.5 million tons. The Musan mine was reportedly undergoing expansion and modernization. The bulk of the remaining output was from the Chaeryong, Hasong, Kaech'on, Komdok, Songnam, Tokhyon, Unyul, and Yongwon mines, all of which were small- to medium-size mines. The iron ore deposits at Toksong and Sohaeri were still undergoing development.

Annual pig iron production capacity was estimated at 3.5 million tons and that of steel semimanufactures at 2.8 million tons. Most of the production was locally consumed. Kim Ch'aek Iron Works in Ch'ongjin was the largest iron and steel complex in North Korea. Kim Ch'aek had two 800-ton blast furnaces, one 1,500-cubic-meter blast furnace, two 100-ton converter units, a hot-rolling mill from the U.S.S.R., and four coke ovens. A hot- and cold-rolling mill of 1-million-ton annual capacity was under construction with Soviet aid. Construction of a fifth coke oven and a storage area for raw materials is in the planning stage.

Hwanghae Iron Works at Songnim had three 250,000-ton blast furnaces, six open-hearth furnaces, and two coke ovens. Kang-

Digitized by Google

son Steel Works at Kangson's affiliate, April 13 Steel Works, had four rotary kilns for the production of granulated iron. The smaller steelworks in North Korea are the Kaech'on Rerolled Steel Plant at Kaech'on-gun, the Songjin Steel Works at Kimch'aek, the Puryong Alloy Plant at Ch'ongjin, and the P'yongyang Steel Plant at P'yongyang. Construction of a steelworks on the lower reaches of the Taedong River was planned. However, no information on the nature and status of this project is available.

Nonferrous Metals.—Lead and zinc continued to be the principal nonferrous metals produced in North Korea. The bulk of the domestic output of lead-zinc ore was from mines at Komdok and Songch'on. The country's lead-zinc smelters are located at Namp'o (zinc), Hamhung (55,000 tons of lead and 80,000 tons of zinc per year), and Munch'on-gun (the Munp'yong refinery, producing 70,000 tons of zinc per year). A lead-zinc refinery in the western district was planned, but construction had not been undertaken.

North Korea produces refined copper mostly from imported concentrate and from indigenous ore. The country's copper refineries are located at Hamhung (the Hungnam refinery, producing 30,000 tons of electrolytic copper per year), Haeju, and Namp'o. A copper refinery was reportedly under construction at Tanch'on-gun.

Small aluminum remelting facilities are located at Chinampo, Hungnam, and Tasado. Domestic requirements for aluminum are met by imports. However, a 20,000-ton-per-year aluminum smelter was planned for construction at Pukch'ang-gun.

North Korea annually provides about 5% of the world production of tungsten. The country also produces small quantities of antimony, cadmium, germanium, gold and silver, indium, lithium, manganese, molybdenum, nickel, and rare earths, but in most cases, information is inadequate to make reliable estimates of output levels.

NONMETALS

Cement.—The annual production capacity for cement using indigenous limestone was around 7 million to 8 million tons. About half of the total output was from the Sunch'on cement plant, the largest cement operation in the country. During the second 7-year plan, the Sunch'on plant was to be expanded to 5 million tons annual capacity. North Korea's cement facilities were as follows:

Plant	Location	Remarks
Ch'ongjin	Ch'ongjin (North Hamgyong).	
Ch'onnae-ri	Ch'onnae-ri (Kangwon)	5 rotary furnaces.
Haeju	Haeju (South Hwanghae)	4 rotary furnaces.
Kangson	Kangson.	
Komusan	Ch'ongjin (North Hamgyong)	2 rotary furnaces.
Kowon	Kowon-gun (South Hamgyong).	
Kujang	Kujang-gun (North P'yongan).	
Madong	Pongsan-gun (North Hwanghae).	
Pihyon	P'ihyon-gun (North P'yongan).	
Pukch'ang	Pukch'ang (South P'yongan).	
Purae-san	Kowon-gun (South Hamgyong)	2 rotary furnaces.
Pusan-ni	Pusan.	
Samhwasong	Munch'on-gun.	
Sinwon	Sinwon-gun (South Hwanghae).	
Sunch'on	Sunch'on-gun (South P'yongan)	3-million-ton-per-year capacity.
Sungho-ri	P'yongyang	4 rotary furnaces; 30,000-ton-per-year capacity.
Tokch'on	Tokch'on-gun (South P'yongan).	
Unsan	Unsan-gun (North P'yongan).	
Yongma	Paegam-gun (Yanggang).	

Fertilizer Materials.—Annual output of natural phosphate for fertilizers was around 450,000 tons. Small- to medium-scale phosphate fertilizer plants are located in almost all of the provinces. Based on Government estimations, North Korea's production level of chemical fertilizers currently ranges between 2.5 million and 3.0 million tons. Hungnam United Fertilizer was the largest producer of chemical fertilizers. Most of the remainder was from plants at Ch'ongsu and Sunch'on.

Digitized by Google

Plant	Location	Remarks
Aoji	Kyonghung-gun	Nitrogenous, phosphatic, ammonium bicarbonate.
Ch'ongjin	Ch'ongjin	Calcium cyanamide.
Ch'ongsu	Ch'ongsu-gun	Phosphatic, trace elements, calcium cyanamide.
Haeju Phosphate	Haeju	Phosphatic.
Haeju Smelting & Refinery	do	Do.
Huich'on	Huich'on	Calcium cyanamide.
Hungnam Smelting & Refinery	Hungnam	Phosphatic.
Hungnam United Fertilizer	Hamhung	Superphosphate, ammonium sulfate, calcium cyanamide, trace elements.
Hwanghae	Songnim	Phosphatic, ammonium sulfate.
Kaech'on	Kaech'on-gun	Calcium cyanamide.
Kanggye Bacterial	Kanggye.	
Kim Ch'aek	Ch'ongjin	Ammonium sulfate.
Munp'yong	Munch'on-gun	Phosphatic, trace elements.
Namp'o	Namp'o	Phosphatic.
Sinch'on	Sinch'on-gun	Calcium cyanamide.
Sinwon	Sinwon-gun	Slaked lime.
Sunch'on	Sunch'on-gun	200,000-ton-per-year capacity for calcium cyanamide.

MINERAL FUELS

Coal.—North Korea's major domestically produced fuel source is coal. Output in 1977 was about 43 million tons, compared with the target of 50 million to 53 million tons set in the fourth economic development plan ending in 1977. The total output was consumed locally for space heating and electricity generation. The remainder was bituminous coal, reportedly of good metallurgical grade. The Chollima Sinch'ang coal mine is the nation's largest producer. Additionally, there are large opencast workings at Yonghung. Additional coal production came from mines at Chik-tong, Ch'onsong, Huksong, Kaech'on, Kangdon, Kangso, Komdok, Kowon, Musan, Taedae-ri, Tokch'on, Toksong, Yongdae, and Yongmun. The mines at Kukdong and Yangjong were reportedly capable of producing up to 1 million tons of coking coal annually. Additionally, the mines at Aoji and Kogonwon were claimed to have produced large quantities of high-grade metallurgical coal.

Petroleum.—There are no known commercial occurrences of oil or natural gas in North Korea. Domestic demand for petroleum has been met through imports, principally from China and the U.S.S.R. A pipeline completed in late 1975 delivers Taching oil from China to North Korea. An oil refinery was built at Namhung to process Chinese crude oil and to provide naphtha feedstock for a petrochemical plant purchased from European concerns in 1971. The oil refinery on the eastern coast, which reportedly came onstream in 1974-75, presumably handles imports of crude oil from the U.S.S.R.

The Mineral Industry of the Republic of Korea

By E. Chin [1]

During the third 5-year economic development plan, the gross national production (GNP) of the Republic of Korea grew at an average annual rate of about 11% between 1972 and 1976. In constant 1970 prices, the GNP in 1977 was $16.9 billion,[2] a real growth of 10.37% over that in 1976. In terms of current prices, the GNP reached $31.5 billion[3] in 1977, an increase of 26% over the 1976 GNP. By sectors, mining and quarrying accounted for only 1% of the GNP in 1977, compared with 29% for manufacturing; 37% for communications, power utilities, and other public services; and 33% for other goods and services. Output in the manufacturing sector was estimated at $9.1 billion in 1977. Minerals-related components in this sector, in million dollars, included chemicals and chemical products, 680; petroleum and coal products, 865; primary metals, 317; and fabricated and assembled metal products, 124. Thus, the Republic of Korea is like a smaller scale Japan, producing large amounts of mineral and metal products but not too many crude minerals.

Production indexes (1975=100) for the major components of the mining, mineral processing, and fuels sectors for the last 5 years follow:[4]

	1973	1974	1975	1976	1977
Mining:					
Coal, anthracite	77	87	100	93	99
Metallic ores	91	95	100	111	121
Nonmetallic ores	84	90	100	117	138
Primary metals:					
Iron and steel	49	94	100	141	171
Nonferrous metals	62	71	100	143	179
Industrial chemicals	68	77	100	124	147

Led by a 29% jump in cost for agricultural and marine food items, wholesale prices rose 9% in 1977, compared with 12% in 1976. Import prices, which nearly doubled between 1972 and 1974, increased only 0.9% during 1977. Consumer prices advanced 10%, resulting chiefly from a 26% increase in the cost of fuel and electricity.

The fourth 5-year economic development plan (1977-81) calls for an average annual economic growth rate of 9.2% during the plan period, whereby the GNP would reach 16,214 billion won (W) in 1981, in 1975 prices.[5] The growth in the primary industry sector was projected at 4% per year, compared with 14.2% for mining and manufacturing and 7.6% for tertiary industries. The population was projected to grow at 1.6% annually, reaching 38.8 million in 1981. Per capita GNP was expected to expand from $847 in 1977 to $1,512 in 1981. Domestic financing of W18,008 billion (1975 prices) was to be invested during the 5-year period for various projects envisaged in the economic development plan. Additionally, inflow of capital from foreign loans and investments was projected to be around $10 billion for the plan period. In 1975 constant prices, exports were to grow at 16% per year, reaching $14.2 billion in 1981, while imports would increase 12% per year to $13.8 billion in 1981. Accordingly, the visi-

Digitized by Google

ble trade balance would sustain a deficit in 1978-79 and yield a surplus beginning in 1980. Employment was to increase by 3.2% annually to 14.8 million in 1981. In particular, employment in the mining-manufacturing sector was to expand by 7.5% per year during the period, creating employment for 1.2 million persons.

Targets of the economic development plan applicable to the mining industry were to complete the basic survey investigation of mineral resources, maximize economic development of mineral resources, reinforce the policy inducing development of mineral resources, and utilize mineral resources for efficient and economic consumption. To reach these goals, assistance and subsidy would be provided to increase production of mineral raw materials for the secondary and tertiary industries; geologic investigation and exploration programs were to be enlarged; systematic efforts were to be made in increasing gold production and in the exploration and development of nuclear fuel minerals; processing facilities were to be upgraded and modernized in order to produce manufactured goods rather than beneficiated mineral raw materials; mine facilities were to be updated with installation of new equipment utilizing modern technology; mining support was to be enhanced by increasing tax exemptions for mining investment and exploration and by other incentives; and lastly, development of foreign mineral resources was to be encouraged. As for coal, Korea's leading mineral product, there was to be an intensification of exploration activities; expansion of production facilities and improvement in extraction technology; establishment of an inducement system to encourage coal mine development; and programs to develop efficient utilization of coal.

Under a long-term energy supply-demand study (1977-81) drafted in 1976, the annual growth rate in demand for energy was estimated at 9%. Total energy demand in 1977 was estimated at 66.6 million tons in terms of standard coal equivalent (SCE) and was projected to reach 93.1 million tons SCE in 1981. In 1977, the domestic configuration of energy demand was estimated as follows, in million tons SCE: Oil, 37.7; hydroelectric and nuclear power, 1.0; charcoal, 6.1; and coal, 21.8. During the fourth economic development period, W355,906 million was to be invested in the development of the coal mining industry; W287,906 million in the oil refining industry; and W2,390 billion for electricity generation and electrification.

On September 10, 1977, the Government's Organization Law was revised and a Ministry of Energy and Resources was established, effective January 1, 1978. The new Ministry was to assume the administrative functions related to resources and energy formerly vested in the Ministry of Commerce and Industry, and will be responsible for developing and controlling mineral and energy resources on a long-term basis for the country. In addition to offices for mine registration, and planning and management, the Ministry consists of five bureaus: Planning, resources development, electricity, petroleum, and coal.

On February 10, 1977, the President disclosed a Government plan to construct a temporary administrative capital south of Seoul. No site was selected for the new capital, and land procurement and construction were not expected to begin until the 1980's. Relocation of the capital was regarded as a means to control the rapidly growing population of Seoul.

Kuma Expressway, which links Taegu, center of the southeastern inland industrial sphere, with Masan, a large free export zone, was opened to traffic on December 17, 1977. Ch'angwon, close to Masan, is a large-scale-machinery industrial complex which is expected to be further enlarged under the heavy industry expansion plan. Kuma Expressway is an 84.5-kilometer, two-lane road. Construction began in June 1976, and total cost of the project was W23.7 billion.

Test operation of the Kori nuclear reactor began on June 19, 1977. Westinghouse Electric Corp. was the main contractor for the installation of the pressurized-water reactor, which has a rated generating capacity of 595,000 kilowatts. The cylindrical reactor containment vessel is 36 meters in diameter and rises 60 meters above ground with 10 meters below ground level. The reactor surface is covered with 3.7-centimeter-thick steel plates, and the outer containment walls consist of 1-meter-thick reinforced concrete. The Kori unit has one high-voltage turbine generator and two low-voltage turbine generators. Power generation cost was estimated at W9.21 per kilowatt-hour, compared with W14.37 for thermal powerplants. The reactor uses enriched uranium-235 as fuel, and 48 tons of enriched uranium have been stockpiled, which is sufficient to fuel the reactor for 3 years. Full operation of the Kori unit was not expected until 1978 because of malfunction of steam pipes.

The Ministry of Energy and Resources

Digitized by Google

proposed the construction of seven additional nuclear power units by 1986. A 678,000-kilowatt reactor was to be constructed in 1982, a 650,000-kilowatt reactor in 1983, a 900,000-kilowatt reactor in 1984, two 900,000-kilowatt reactors in 1985, and two more 900,000-kilowatt reactors by the end of 1986.

The Value-Added Tax Law, promulgated on December 22, 1976, became effective on July 1, 1977. Seven indirect taxes (business, commodity, textile products, electricity and gas, admission, petroleum products, and transportation) and one local tax (restaurant service) were absorbed into the newly created tax system. A uniform tax rate of 13% was to be imposed, which, however, was reduced to 10%. Items exempt from the value-added tax included daily necessities such as foods, social welfare services, export goods, and foreign-exchange-earning goods and services. The major objectives of the new tax system were to simplify tax collection and administration, promote exports and investments, abolish overlapping tax assessments, encourage formation of integrated enterprises, and eliminate tax evasion.

On November 6, 1977, a fire swept through a coal pit in the Changsung mine, Kangwon Province, injuring 80 miners and killing 12. The fire, caused by an explosion of a high-voltage power transformer situated in a shaft 350 meters below the surface, was brought under control on November 22. The Changsung mine, owned by the state-run Dai Han Coal Corp. (DHCC), produces about 1.9 million tons of coal per year and employs about 5,000 miners.

During the year, construction activities were brisk because of expanded activities by individual, private, and Government contracts in various projects. Construction permits approved were classified as follows, in square meters: 12.9 million for 117,801 new housing units; 3.6 million for 13,931 commercial and service structures; 3.4 million for 3,595 industrial structures; and 2.4 million for 7,126 educational and other structures. Construction of 10 plants was completed during the year, including a 250,000-ton steelmaking plant at Ch'angwon Machinery Industrial Complex, and a 50,000-ton polyvinyl chloride plant and a 6,000-ton acrylonitrile butadiene styrene plant at Yochon Petrochemical Industrial Complex. The Ministry of Construction estimated that foreign contracts totaling $3.4 billion were won by Korean firms in 1977. The number of domestic firms involved in overseas construction projects increased from 53 in 1976 to 64 in 1977, involving various projects in 26 foreign countries.

In early December, the Government announced measures to liberalize import restrictions in 321 commodity items, which would be put into effect beginning on May 1, 1978, until the end of 1982. Under the first stage of the new import liberalization policy (May 1 to December 31, 1978), 133 items would be freed from the import-prohibited or import-restricted category. The remaining 188 liberalizations would occur during 1979-82. On December 22, 1977, Korea's exports reached the $10 billion mark, making Korea 26th in the list of the world's top exporting countries.

On December 16, 1977, the National Assembly approved legislation to extend the Republic of Korea's territorial waters from 3 miles to 12 miles.

PRODUCTION

The Republic of Korea is a major world producer of anthracite, graphite, kaolin, pyrophyllite, talc, and tungsten.[e] Other mineral commodities mined locally include copper, iron ore, fluorspar, lead, zinc, and limestone. The overall mining production index in 1977 was 159.3 (1970=100), compared with 136.5 for metallic minerals, 228.8 for nonmetallic minerals, and 139.8 for coal. In addition, Korea produces primary metals, such as aluminum, copper, and iron and steel, from imported ores and concentrates. Domestic production of limestone is significant, about 22 million tons, and is used primarily in cement manufacture. The domestic capacity to produce cement is around 16 million tons. About three-quarters of the cement production is consumed domestically with the remainder exported.

There was no domestic production of oil and natural gas. In addition to coal and hydropower and nuclear power generation, Korea imports crude petroleum and coal to meet its energy demands. The production index for oil refining in 1977 was 130.2 (1975=100), an increase of 11.4% from the previous year. Total oil refining capacity at yearend 1977 was 435,000 barrels per day. The principal petroleum refinery products produced during the year were bunker oil, diesel oil, naphtha, and gasoline, in that order.

TRADE

Overall trade for the Republic of Korea in 1977 was close to $20.86 billion; the value of imports was $10.81 billion, compared with $10.05 billion for exports.[7] By area, exports to Far East and Middle East countries were valued at $4.3 billion; to North America, $3.5 billion; Europe, $1.86 billion; Africa, $0.3 billion; Oceania, $0.1 billion; and South America, $0.05 billion. By far the largest individual export destinations were the United States, $3.1 billion, and Japan, $2.1 billion. By commodity classifications, exports of textile were $2.9 billion, by far the largest category, followed by animal and vegetable products, $1.1 billion; and mechanical and electrical machinery and appliances, $1.0 billion. The value of exports of metals and semimanufactures in 1977 was $995.8 million; for mineral products, $358.1 million; and for chemicals, $211.9 million.

Sales of domestically produced minerals and metals to foreign markets increased 27.3% over the 1976 level in 1977, and 38.5% over the 1977 export target set by the Government in the current economic plan. By value, the leading mineral export commodities included tungsten, talc, zinc ore, kaolin, and anthracite.

Imports by area in 1977 were as follows, in billion dollars: Far East and Middle East countries, 6.7; Europe, 0.9; North America, 2.6; South America, 0.07; Africa, 0.08; and Oceania, 0.3. Imports of mineral products were the largest category by value; receipts of mineral fuels at $2.2 billion constituted 91% of the total imported in this class. Imports of other major commodity categories included mechanical and electrical machinery and appliances, $2.3 billion; animal and vegetable products, $0.93 billion; and chemicals, $0.86 billion.

COMMODITY REVIEW[8]

METALS

Aluminum.—Total output of primary aluminum was by one company, Aluminum of Korea, Ltd. (Koralu) at its reduction plant at Ulsan. Koralu, a 50-50 joint venture of the Korean Industrial Bank and Péchiney Ugine Kuhlmann (PUK), has an annual production capacity of 18,000 tons of aluminum metal. Koralu imports alumina for its smelter and in 1977 received 197,064 tons from Japan and 168,930 tons from Malaysia. The domestic demand for aluminum was estimated at 65,000 tons per year. During the year, receipts of unwrought metal totaled 68,337 tons, mostly from Japan, Canada, and Bahrain. The Korean Industrial Bank was negotiating with PUK for possible expansion of the Ulsan smelter capacity to 72,000 tons per year or for the construction of a 100,000-ton-per-year smelter at Onsan.

Copper.—Production of copper concentrate in 1977 was almost 12,000 tons, averaging 15% copper. The Kumpuk copper mine at Kyunsang Nando accounted for the bulk of the Nation's copper ore output. Imports of copper ores and concentrates totaled 55,766 tons, of which the Philippines supplied 66%; waste and scrap imports of 54,360 tons were mostly from the United States; and unwrought metal and ingot imports totaled 14,093 tons, of which 58% was from Japan. Close to 75% of the total production of electrolytic copper was by the Changhang smelter owned by Korea Mining & Smelting Co., Ltd., which has an annual capacity of 37,700 tons of metal.

To meet increasing demand for copper, an 80,000-ton-per-year smelter-refinery was being constructed by a consortium of United Kingdom, Belgium, and Finnish interests at the nonferrous metals industrial complex at Onsan. By yearend, construction was well underway and on schedule, and commissioning of the $180 million smelter-refinery was expected in early 1979. Onsan Copper Refinery Co., Ltd., is owned 50% by the Korea Development Bank, with the remaining equity held by three private companies. Onsan Copper will produce cathode copper, sulfuric acid, gold, and silver.

Iron and Steel.—Mine production of iron ore was around 791,000 tons in 1977. Almost half of the domestic mine output was from the Yangyang mine in Kangwon Province operated by Dai Han Iron Mining Co., Ltd. Domestic mine production constitutes about 20% of Korea's requirement for iron ore. In 1977, Korea imported 3.1 million tons of hematite, mostly from Australia and India, and 0.5 million tons of magnetite, primarily from Peru, Australia, and Mexico. Imports of coking coal totaled 2.0 million tons, supplied mostly by Australia, the United States, and Canada, in that order.

Pohang Iron and Steel Co. (POSCO), with a production capacity of 2.6 million tons of steel per year, dominates Korea's iron and steel industry. The other producers were Dongkuk Steel Mill Co., Inchon Iron Works Co., Kuck Dong Steel Co., and Pusan Iron and Steel Co. Total industry output in 1977 included 2.4 million tons of pig iron and 2.7 million tons of crude steel.

POSCO, the only integrated steel operation in the country, completed its second-stage expansion in May 1976 with the installation of blast furnace No. 2, bringing its crude steel capacity up to 2.6 million tons per year. Posco's facilities include blast furnace No. 1 with a daily capacity of 2,600 tons, blast furnace No. 2 with 3,880 tons, a steelmaking plant with three 100-ton converters, a continuous-casting mill, and hot-rolling and cold-rolling mills. The third-stage expansion program, estimated to cost $1.3 billion, began in October 1976 with the construction of blast furnace No. 3 (loading capacity of 3,795 cubic meters), which would raise POSCO's steel output capacity to 5.5 million tons per year by 1980. A steelmaking mill with two 300-ton converters is also under construction, along with the No. 2 blooming and slabbing mill with five rolling machines, each with a motor capacity of 12,000 kilowatts; and the No. 2 plate mill, which can annually produce 1.4 million tons of plates with a maximum diameter of 4.2 meters and a maximum weight of 25 tons.

A fourth-stage expansion is planned whereby POSCO's crude steel output will reach 8.5 million tons in the 1980's. Construction in the fourth phase includes blast furnace No. 4, a second hot-rolling mill, and the No. 2 continuous-casting mill.

Lead and Zinc.—Young Poong Mining Co., Ltd. (Young Poong) is the largest lead and zinc producer in Korea, operating mines at Yeonhua, Boonpyong, and Ulgen. Young Poong produces all of the country's output of lead concentrate and about 81% of

Digitized by Google

the zinc concentrate. Lead metal output, around 6,700 tons, was all by the Changhang smelter of Korea Mining & Smelting Co., Ltd. Young Poong operates a zinc refinery at Sokpo, and output of 1977 was estimated at 32,800 tons. It also exports zinc concentrate to Japan for refining. Korea Zinc Co., which is constructing a 50,000-ton-per-year refinery at Onsan, is owned principally by Young Poong Co. (44.4%), Young Poong Mining Co. (20.5%), and the International Finance Corp. (20.81%). The zinc concentrates being exported to Japan will be treated at the new facility when completed. In addition to zinc, the new facility will have the annual capacity to produce 100,000 tons of sulfuric acid and 300 tons of cadmium metal. The estimated cost of the smelter was $70 million, which included ore storage facilities, a roaster (350 tons per day), and a casting shop. Another 10,000 tons of zinc-refining capacity was expected to be added in 1981.

Tungsten.—Total production of tungsten concentrate, average grade of 0.8%-1.0% WO_3, was estimated at 4,746 tons. The Sangdong mine of Korea Tungsten Mining Co., Ltd., produced the bulk of the country's tungsten. The remainder of the output was distributed as follows, in tons: Chungyang Co., 135; San-Nae mine, 75; Okbang Mining Co., Ltd., 71; Wol-Ak mine, 65; Ssang, 69; Daewha mine, 19; and other, 41. The mill at Sangdong can process 2,000 tons of ore per day; the concentrate produced is shipped to Korea Tungsten's plant at Taegu where it is processed to produce tungsten powder, carbide, and ammonium paratungstate. Production of ammonium paratungstate totaled 2,016 tons; tungsten powder, 645 tons; and tungsten carbide, 189 tons. Korea's production of tungsten constitutes about 60% of the total world output.

Other Metals.—During 1977, 134 tons of bismuth metal was produced as a byproduct of tungsten processing by Korea Tungsten Mining Co., Ltd. Production of silver metal totaled 2.1 million troy ounces. The bulk of the output was by the Changhang smelter of Korea Mining & Smelting and the Boonpyong operations of Young Poong Mining. The country's output of gold metal was 21,380 troy ounces. Close to 65% of the total production was from Korea Mining's Changhang smelter. Output of 40% manganese ore was 664 tons and of molybdenite, 187 tons. Mine production of other metal values during the year included minor amounts of arsenic and tin.

NONMETALS

Cement.—Cement production by 10 plants of 6 companies reached 14 million tons in 1977. Ssangyong Cement Industries Co., Ltd., the largest cement manufacturer, produced about one-third of the country's total output, followed by Tong Yang Cement Co., with about 2.6 million tons; Hanil Cement Manufacturing Co., Ltd., 2.0 million tons; Asia Cement Manufacturing Co., Ltd., 1.4 million tons; and Sung Shin Cement Co., 1.3 million tons. The smaller companies, Hyundai Cement Co. and Korea Cement Co., each produced less than 1 million tons during the year.

Total industry kiln capacity at the end of 1977 was estimated at 16.3 million tons. Under the fourth 5-year plan, domestic production was expected to reach 23 million tons by 1980. Ssangyong Cement was expanding its Tonghae plant from 2.9 million tons to 5.6 million tons. Additionally, Sung Shin Cement began the expansion of its plant at Tanyang to increase capacity from 1 million tons to 2.1 million tons.

During the year, Korea exported close to 1 million tons of cement clinker, primarily to Singapore, Hong Kong, and Bangladesh. Shipments of portland cement totaled 1.8 million tons, with India, Saudi Arabia, Kuwait, and Iran as the principal destinations.

Fertilizer Materials.—Production of urea totaled 1.1 million tons in 1977; compound fertilizers 1.1 million tons; and fused magnesium phosphate, 111,125 tons. Fertilizer manufacturers included Chinhae Chemical Co., Ltd., Han Kook Caprolactan Co., Ltd., Korea General Chemical Corp. (state-owned), Kyunki Chemical Co., Ltd., POSCO, Pungnong Chemical Co., Ltd., and Yong Nam Chemical Co., Ltd. During the year, exports of urea totaled 463,441 tons; fertilizers containing nitrogen, phosphorus, and potassium, 342,326 tons; and fertilizers containing nitrogen and phosphorus, 68,319 tons. The principal destinations were Bangladesh, Pakistan, and the Philippines.

Namhai Chemical Co. started operation of one of two 90-ton-per-day ammonia plants being built at its major fertilizer complex in Yeochem in February 1977. A 1,000-ton-per-day urea plant was to be commissioned shortly afterwards. Other parts of the complex include a 660-ton-per-day phosphoric acid plant, two 1,080-ton-per-day nitrogen-phosphorous-potassium granulated fertilizer plants, two 1,050-ton-per-day sulfuric acid plants, and nitric acid and ammonium nitrate units.

Digitized by Google

Other Nonmetals.—Due to greater demand for cement for construction and export, limestone production increased 19% to 22.7 million tons in 1977. Production of kaolin clay was 534,591 tons. Production of talc and pyrophyllite was 171,926 tons and 443,304 tons, respectively. Production of other nonmetallic minerals during 1977 included marine salt, amorphous and crystalline graphite, feldspar, fluorite, diatomaceous earth, asbestos, barite, and andalusite.

MINERAL FUELS

Coal.—Under the Government's energy supply-demand program (1977-81), the average increase in coal production was set at 9.1% annually. The output of anthracite was projected to increase from 21.7 million tons in 1977 to 27.9 million tons in 1981. However, anthracite production was only 17.3 million tons in 1977, a 5% increase over the 1976 output. To encourage growth in coal production, the Government's program called for investing W180.4 billion and $17.6 million in foreign exchange funds in the coal mining industry.

Virtually all of the country's production was domestically consumed, primarily for space heating. The Government-owned DHCC produced 26% of the country's anthracite output. The major mines worked by DHCC are Jang Seong, Do Gye, Ham Baeg, Hwa Sun, and Eun Seong. Total coal reserves in Korea were estimated to be 1.4 billion tons. DHCC holds about 25% ownership of the total reserves; the remainder are in private hands.

Petroleum.—The Republic of Korea imports all of its oil requirements, mostly in the form of crude petroleum, principally from Saudi Arabia. Other suppliers include Iran and Kuwait. In 1977, 22.9 million tons of crude oil was imported, valued at $2.2 billion.

At the end of 1977, South Korea's total oil-refining capacity by three refineries was 435,000 barrels per day. Korea Oil Corp. (KOCO) operates an oil refinery with a daily refining capacity of 215,000 barrels at the Ulsan Petrochemical Industrial Complex. The 60,000-barrel-per-day refinery of Kyong-In Energy Co. is at Inchon. Honam Oil Refinery Co. operates its 160,000-barrel-per-day refinery on the south coast of Yosu.

During 1977, KOCO was continuing an expansion project to increase its daily refining capacity by 65,000 barrels. Work was continuing on the construction of a new 60,000-barrel-per-day refinery at the nonferrous metals industrial complex at Onsan. Construction on this refinery, which is a joint venture between the Ssangyong Business Group and Iranian interests, began in October 1976. Completion of this refinery was scheduled for 1978.

The Mineral Industry of Kuwait

By T. John Rowland, Jr.[1]

In 1977, Kuwait ranked fourth in the Middle East and eighth in the world in terms of petroleum production and third in the world in terms of proven petroleum reserves. Petroleum accounted for nearly 90% of Government revenues, and hydrocarbons (crude and refined petroleum and natural gas) accounted for about 94% of total Kuwaiti exports.

Kuwait, highly developed by regional standards, increased allocations for ordinary budget expenditures from $3.1 billion[2] for fiscal year 1977 to $5.1 billion for fiscal year 1978.[3] The Government undertook a variety of major development projects including expansion of electricity generation and water desalination capacities ($1.2 billion), telecommunications and ports ($750 million), and tanker purchases ($300 million). A draft of the 5-year plan (1977-81) allocated $16.6 billion for development expenditures.

Although the nonfuel industries contributed a very small portion of the 1977 gross domestic product (GDP) of $15 billion, Kuwait was rapidly industrializing with the assistance of the Industrial Bank of Kuwait, which conducted feasibility studies and financed projects. Kuwait's foreign assets surpassed $20 billion in 1977.

The Kuwait-based Arab Fund for Economic and Social Development (AFESD) signed 15 loan agreements for projects in Arab countries totaling $371 million in 1977. The 62% increase over the 1976 loan commitments brought total AFESD loans to nearly $1.06 billion. Egypt, Syria, Jordan, and Lebanon were recipients of significant amounts of Kuwaiti economic aid during 1977.

The Kuwait Oil Co., Ltd. (KOC) awarded Entrepose S.A. (France) a $27 million contract for the improvement of loading facilities at KOC's Sea Island oil export terminal. Scheduled for completion in 1979, the expansion will raise the handling capacity of the Sea Island terminal by 180,000 deadweight tons to a total of 500,000 deadweight tons.

After several months of negotiations, the Government fully nationalized American Independent Oil Co.'s (Aminoil) assets in the Kuwait Saudi Arabia Partitioned Zone by nullifying Aminoil's 29-year-old concession. Kuwait Wafra Oil Co., a new State company, took over the operation, bringing to four the number of State petroleum companies. KOC accounted for 89% of petroleum production and was nationalized by decree in 1975. The other State enterprises were Kuwait Petrochemical Industries Co. (KPIC) and Kuwait National Petroleum Co. (KNPC). KPIC was primarily responsible for petrochemical production, and KNPC controlled over 75% of Kuwaiti refinery capacity. The nationalization of Aminoil affected a modest output involving the company's share of a joint operation with Getty Oil Co. (GOC) at the onshore fields of Wafra and South Umm Gudair.

PRODUCTION AND TRADE

Petroleum production averaged 1.97 million barrels per day in 1977, representing a decline of 8% from that of the previous year. Kuwait lowered its price by 10 cents

Digitized by Google

per barrel in September because of large stocks and slow demand. Production from the Partitioned Zone was shared equally between Kuwait and Saudi Arabia. The two-tier price system of the Organization of Petroleum Exporting Countries (OPEC) and large oil stocks resulted in a decline in Arabian Oil Co. (AOC) production. Production in the Partitioned Zone averaged nearly 366,000 barrels per day during 1977.

Gross Natural gas production in 1977 was 363 billion cubic feet, decreasing 8.4% from the 1976 level. Utilization of gas increased 7% over that of 1976. The main improvement in usage was by state enterprises, such as desalination and powerplants, with consumption rising from 108 billion cubic feet in 1976 to 126 billion cubic feet in 1977.

Kuwait's output of refined petroleum products during 1977 averaged 352,300 barrels per day, a decrease of 20.5% from 1976 production. This output represented 58% of the total capacity of Kuwait's three refineries: The KOC refinery at Mina al Ahmadi (285,000 barrels per day), the KNPC refinery at Shuaiba (180,000 barrels per day), and the Kuwait Wafra Oil Co. refinery at Mina Abd Allah (144,000 barrels per day). In addition, Kuwait's share of output from the Partioned Zone averaged 33,200 barrels per day.

Crude oil exports totaled over 554 million barrels, and refined products, including liquefied natural gas, amounted to 118 million barrels in 1977. Crude oil was exported primarily to the Far East (47%) and Europe (38%). Japan remained the major importer of Kuwaiti crude oil, increasing its share to 25% of exports. Other major importers of Kuwaiti crude oil were the United Kingdom, the Netherlands, the Republic of Korea, Italy, and Brazil. Exports of refined products were destined principally for the Far East (71%), but significant amounts also went to Europe (14%) and the Middle East (10%). The United States received about 1% of Kuwaiti refinery exports. Japan was the largest single importer, accounting for 31% of total exports of refined products.

COMMODITY REVIEW

NONMETALS

Cement.—Kuwait Cement Co. (KCC) produced cement from raw materials imported from Iraq. Plant facilities were expanded in 1977 to increase production capacity to 1 million tons per year. KCC entered joint venture arrangements with other Arab countries during 1977. The company reached a preliminary agreement with the Omani Government to produce clinker and cement from local raw materials in Oman. In Saudi Arabia, KCC agreed to construct a cement plant in which it would be a 45% shareholder. Kuwait was to receive 1,000 tons per day of cement and 4,000 tons per day of clinker from the Saudi plant.

Salt.—The salt and chlorine plant owned and operated by KPIC produced the following products during 1977: Chlorine, caustic soda, table salt, hydrochloric acid, sodium hypochlorite, hydrogen, and distilled water. New container equipment for sodium hypochlorite was to improve the competitive stature of the product on local and foreign markets.

MINERAL FUELS

Natural Gas.—By yearend, associated natural gas production totaled 363 billion cubic feet, of which KOC produced 93%. Natural gas was used for reinjection in oilfields, fertilizer production, water distillation, and power generation. Construction continued on the Kuwait Gas Utilization Project, with completion scheduled for 1978. In April, negotiations were begun between the Government and 20 international firms from Japan, the United States, and Europe for marketing the natural gas. The $1 billion project was designed to collect and process high- and low-pressure associated gas from 25 oil-gathering stations located in major Kuwaiti oilfields.

KOC drilled a deep test well to a targeted 20,000 feet in Burgan Field to probe possible hydrocarbon regions underlying the current oil-producing Burgan formation at 4,800 feet. The well was designed to explore the Persian Khuff Zone which has been a major source of non-associated gas in Saudi Arabia, Bahrain, and Iran. AOC was delineating the Dorra Field located north of Hout in the partitioned Neutral Zone which was known to contain large reserves of non-associated natural gas.

Petrochemicals.—KPIC produced ammonia, urea, and sulfuric acid during 1977. Ammonium sulfate was not produced because of the prevailing low prices on the international market. The sulfuric acid unit operated for a period of approximately 4 weeks with output destined for the domestic market, Jordan, and Qatar. Production of liquid ammonia decreased 1%, and urea production increased 4% in 1977. The results of a feasibility study were favorable for construction of a 1,000-ton-per-day ammonia plant at the port of Shuaiba. The new plant would increase ammonia production capacity at Shuaiba to 3,000 tons per day. Associated gas from area oilfields would supply raw materials for the plant. The plant's output was destined for export. KPIC increased urea production capacity to 2,500 tons per year in early 1977. Work continued on construction of an extraction unit for dissolved urea and ammonia in the waste water of the urea plant. Completion of the project was expected during 1978.
